

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

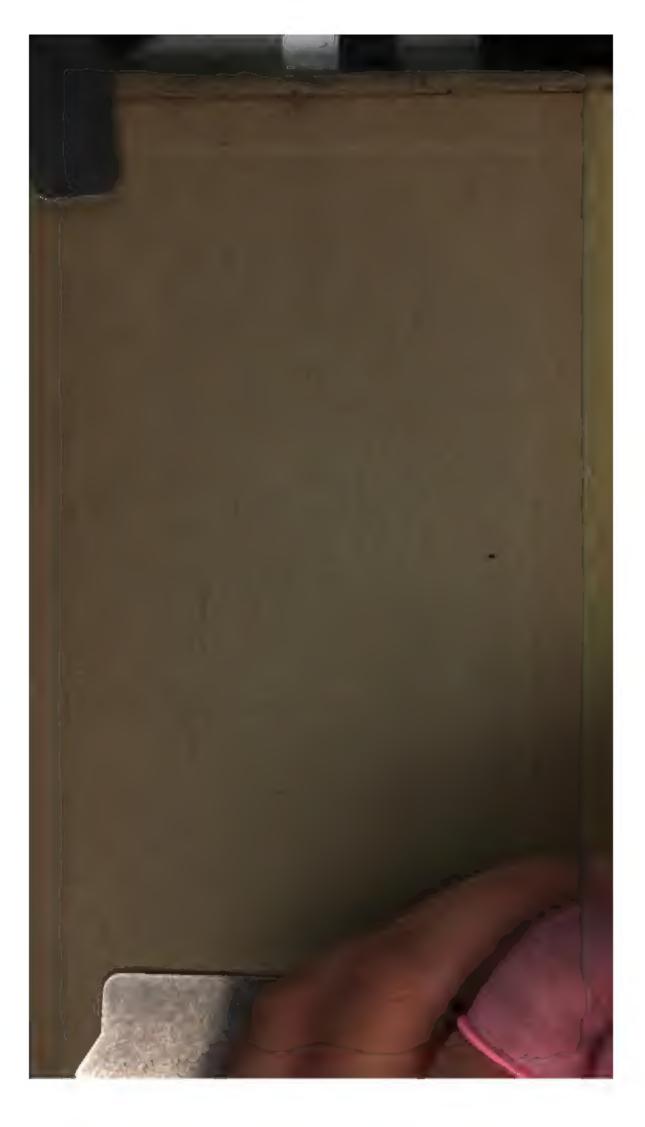

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + Make non-commercial use of the files We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + Maintain attribution The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + Keep it legal Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

A

HISTORY

OF THE

INDUCTIVE SCIENCES,

RTC.

VOLUME THE THIRD.

Of mighty Nature, if 'twas ever meant
That we should pry far off and be unraised,
That we should pore, and dwindle as we pore,
Viewing all objects unremittingly
In disconnexion dead and spiritless;
And still dividing, and dividing still,
Break down all grandeur, still unsatisfied
With the perverse attempt, while littleness
May yet become more little; waging thus
An impious warfare 'gainst the very life
Of our own souls.

WORDSWORTH, Excursion.

BOOK XI.

THE

MECHANICO-CHEMICAL SCIENCES.

HISTORY OF ELECTRICITY.

PARVA metu primo: mox sese extollit in auras, Ingrediturque solo, et caput inter nubila condit. Æn. iv. 176.

A timid breath at first, a transient touch,
How soon it swells from little into much!
Runs o'er the ground, and springs into the air,
And fills the tempest's gloom, the lightning's glare;
While denser darkness than the central storm
Conceals the secrets of its inward form.

INTRODUCTION.

Of the Mechanico-Chemical Sciences.

INDER the title of Mechanico-Chemical Sciences, I include the laws of Magnetism, Electricity, Galvanism, and the other classes of phenomena closely related to these, as Thermo-electricity. This group of subjects forms a curious and interesting portion of our physical knowledge; and not the least of the circumstances which give them their interest, is that double bearing upon mechanical and chemical principles, which their name is intended to imply. Indeed, at first sight they appear to be purely Mechanical Sciences; the attractions and repulsions, the pressure and motion, which occur in these cases, are referrible to mechanical conceptions and laws, as completely as the weight or fall of terrestrial bodies, or the motion of the moon and planets. And if the phenomena of magnetism and electricity had directed us only to such laws, the corresponding sciences must have been arranged as branches of mechanics. But we find that, on the other side, these phenomena have laws and bearings of a kind altogether different. Magnetism is associated with Electricity by its mechanical analogies; and, more recently, has been discovered to be still more closely connected with it by physical influence; electric is identified with galvanio agency; but in galvanism, decomposition, or some action of that kind, universally appears; and these appearances lead to very general laws. Now composition and decomposition are the subjects of Chemistry; and thus we find that we are insensibly but irresistibly led into the domain of that science. The highest generalizations to which we can look, in advancing from the elementary facts of electricity and galvanism, must involve chemical notions; we must therefore, in laying out the platform of these sciences, make provision for that convergence of mechanical and chemical theory, which they are to exhibit as we ascend.

We must begin, however, with stating the mechanical phenomena of these sciences, and the reduction of such phenomena to laws. In this point of view, the phenomena of which we have to speak are those in which bodies exhibit attractions and repulsions, peculiarly determined by their nature and circumstances; as the magnet, and a piece of amber when rubbed. Such results are altogether different from the universal attraction which, according to Newton's discovery, prevails among all particles of matter, and to which cosmical phenomena are owing. But yet the difference of these special attractions, and of cosmical attraction, was at first so far from being recognized, that the only way in which men could be led to conceive or assent to an action of one body upon another at a distance, in cosmical cases, was by likening it to magnetic attraction, as we have seen in the history of Physical Astronomy. And we shall, in the first part of our account, not dwell much upon the peculiar conditions under which bodies are magnetic or electric, since these conditions are not readily reducible to mechanical laws; but, taking the magnetic or electric character for granted, we shall trace its effects.

The habit of considering magnetic action as the type or general case of attractive and repulsive agency, explains the early writers having spoken of Electricity as a kind of Magnetism. Thus Gilbert, in his book De Magnete (1600), has a chapter, De coitione Magnetica, primumque de Succini attractione, sive verius corporum ad Succinum applicatione. The manner in which he speaks, shows us how mysterious the fact of attraction then appeared; so that, as he says, 'the magnet and amber were called in aid by philosophers as illustrations, when our sense is in the dark in abstruse inquiries, and when our reason can go no further.' Gilbert speaks of these phenomena like a genuine inductive philosopher, reproving those who before him

¹ Lib. ii. cap. 3.

² De Magnete, p. 48.

had 'stuffed the booksellers' shops by copying from one another extravagant stories concerning the attraction of magnets and amber, without giving any reason from experiment. He himself makes some important steps in the subject. He distinguishes magnetic from electric forces, and is the inventor of the latter name, derived from fixerpor, electron, amber. He observes rightly, that the electric force attracts all light bodies, while the magnetic force attracts iron only; and he devises a satisfactory apparatus by which this is shown. He gives a considerable list of bodies which possess the electric property; 'Not only amber and agate attract small bodies, as some think, but diamond, sapphire, carbuncle, opal, amethyst. Bristol gem, beryl, crystal, glass, glass of antimony, spar of various kinds, sulphur, mastic, sealing-wax, and other substances which he mentions. Even his speculations on the general laws of these phenomena, though vague and erroncous, as at that period was unavoidable, do him no discredit when compared with the doctrines of his successors a century and a half afterwards. But such speculations belong to a succeeding part of this history.

In treating of these Sciences, I will speak of Electricity in the first place, although it is thus separated by the interposition of Magnetism from the succeeding subjects (Galvanism, &c.) with which its alliance seems, at first sight, the closest, and although some general notions of the laws of magnets were obtained at an earlier period than a knowledge of the corresponding relations of electric phenomena; for the theory of electric attraction and repulsion is somewhat more simple than of magnetic; was, in fact, the first obtained; and was of use in suggesting and confirming

the generalization of magnetic laws.

³ De Maguete, p. 53.

⁴ lb. p. 48.

CHAPTER I.

DISCOVERY OF LAWS OF ELECTRIC PHENOMENA.

17E have already seen what was the state of this branch of knowledge at the beginning of the seventeenth century, and the advances made by Gilbert. We must now notice the additions which it subsequently received, and especially those which led to the discovery of general laws, and the establishment of the theory; events of this kind being those of which we have more peculiarly to trace the conditions and causes. Among the facts which we have thus especially to attend to, are the electric attractions of small bodies by amber and other substances when rubbed. Boyle, who repeated and extended the experiments of Gilbert, does not appear to have arrived at any new general notions; but Otto Guericke of Magdeburg, about the same time, made a very material step, by discovering that there was an electric force of repulsion as well as of attraction. He found that when a globe of sulphur had attracted a feather, it afterwards repelled it, till the feather had been in contact with some other body. This, when verified under a due generality of circumstances, forms a capital fact in our present subject. Hawkesbee, who wrote in 1709 (Physico-Mechanical Experiments,) also observed various of the effects of attraction and repulsion upon threads hanging loosely. But the person who appears to have first fully seized the general law of these facts, is Dufay, whose experiments appear in the Memoirs of the French Academy, in 1733, 1734, and 1737.1 'I discovered,' he says, 'a very simple principle, which accounts for a great part of the irregularities, and, if I may use the term, the caprices that seem to accompany most of the experiments in electricity. This principle is, that electric bodies attract all those that are not so, and repel them

¹ Priestley's History of Electricity, p. 45, and the Memoirs quoted.

as soon as they are become electric by the vicinity or contact of the electric body Upon applying this principle to various experiments of electricity, any one will be surprized at the number of obscure and puzding facts which it clears up.' By the help of this principle, he endeavours to explain several of Hawkes-

bee's experiments.

A httle anterior to Dufay's experiments were those of Grey, who, in 1729, discovered the properties of conductors. He found that the attraction and repulsion which appear in electric bodies are exhibited also by other bodies in contact with the electric. In this manner he found that an ivory ball, connected with a glass tube by a stick, a wire, or a packthread, attracted and repelled a feather, as the glass itself would have done. He was then led to try to extend this communication to considerable distances, first by ascending to an upper window and hanging down his ball, and, afterwards, by carrying the string horizontally sup-As his success was complete in ported on loops. the former case, he was perplexed by failure in the latter; but when he supported the string by loops of ailk instead of hempen cords, he found it again become a conductor of electricity. This he ascribed at first to the smaller thickness of the silk, which did not carry off so much of the electric virtue; but from this explanation he was again driven, by finding that wires of brass still thinner than the silk destroyed the effect. Thus Grey perceived that the efficacy of the support depended on its being silk, and he soon found other substances which answered the same purpose. The difference, in fact, depended on the supporting substance being electric, and therefore not itself a conductor; for it soon appeared from such experiments, and especially2 from those made by Dufay, that substances might be divided into electrics per se, and nonelectrics, or conductors. These terms were introduced by Desaguliers, and gave a permanent currency to the results of the labours of Grey and others.

Mém. Acad. Par. 1734.

Priestley, p. 66.

Another very important discovery belonging to this period is, that of the two kinds of electricity. This also was made by Dufay. 'Chance,' says he, 'has thrown in my way another principle more universal and remarkable than the preceding one, and which casts a new light upon the subject of electricity. The principle is, that there are two distinct kinds of electricity, very different from one another; one of which I call vitreous, the other resinous, electricity. The first is that of glass, gems, hair, wool, &c.; the second is that of amber, gum-lac, silk, &c. The characteristic of these two electricities is, that they repel themselves and attract each other' This discovery does not, however, appear to have drawn so much attention as it deserved. It was published in 1735; (in the Memoirs of the Academy for 1733;) and yet in 1747, Franklin and his friends at Philadelphia, who had been supplied with electrical apparatus and information by persons in England well acquainted with the then present state of the subject, imagined that they were making observations unknown to European science, when they were led to assert two conditions of bodies, which were in fact the opposite electricities of Dufay, though the American experimenters referred them to a single element, of which electrized bodies might have either excess or defect. 'Hence,' Franklin says, 'have arisen some new terms among us: we say B, who receives a spark from glass, 'and bodies in like circumstances, is electrized positively; A, who communicates his electricity to glass, 'negatively; or rather B is electrized plus, A minus.' Dr. (afterwards Sir William) Watson had, about the same time, arrived at the same conclusions, which he expresses by saying that the electricity of A was more rare, and that of B more dense, than it naturally would have been 4 But that which gave the main importance to this doctrine was its application to some remarkable experiments, of which we must now speak,

Electric action is accompanied, in many cases, by light and a crackling sound. Otto Guericke⁵ observes

⁴ Prestley, p. 115. * Experimenta Maydeburgica, 1672, lib. iv. cap. 15.

that his sulphur-globe, when rubbed in a dark place. gave faint flashes, such as take place when sugar is crushed. And shortly after, a light was observed at the surface of the mercury in the barometer, when shaken, which was explained at first by Bernoulli, on the then prevalent Cartesian principles; but, afterwards, more truly by Hawkesbee, as an electrical phenomenon. Wall, in 1708, found sparks produced by rubbing amber, and Hawkesbee observed the light and the enapping, as he calls it, under various modifications, But the electric spark from a living body, which, as Priestley says,6 'makes a principal part of the diversion of gentlemen and ladies who come to see experiments in electricity,' was first observed by Dufay and the Abbé Nollet. Nollet says? he 'shall never forget the surprize which the first electric spark ever drawn from the human body excited, both in M. Dufay and in himself,' The drawing of a spark from the human body was practised in various forms, one of which was familiarly known as the 'electrical kiss.' Other exhibitious of electrical light were the electrical star, electrical rain, and the like.

As electricians determined more exactly the conditions of electrical action, they succeeded in rendering more intense those sudden actions which the spark accompanies, and thus produced the electric shock. This was especially done in the Leyden phial. This apparatus received its name, while the discovery of its property was attributed to Cunæus, a native of Leyden, who, in 1746, handling a vessel containing water in communication with the electrical machine, and happening thus to bring the inside and the outside into connexion, received a sudden shock in his arms and breast. It appears, however, that a shock had been received under nearly the same circumstances in 1745, by Von Kleist, a German prelate, at Camin, in Pomerama. The strangeness of this occurrence, and the

⁶ P p. 47.

Priestley, p. 47. Nollet, Legons de Physique, vol. vi. p 408.

^{*} Fucher, v. 490.

auddenness of the blow, much exaggerated the estimate which men formed of its force. Muschenbroek, after taking one shock, declared he would not take a second for the kingdom of France; though Boze, with a more magnanimous spirit, wished? that he might die by such a stroke, and have the circumstances of the experiment recorded in the Memoirs of the Academy. But we may easily imagine what a new fame and interest this discovery gave to the subject of electricity. It was repeated in all parts of the world, with various modifications; and the shock was passed through a line of several persons holding hands; Nollet, in the presence of the king of France, sent it through a circle of 180 men of the guards, and along a line of men and wires of goo toises; 10 and experiments of the same kind were made in England, principally under the direction of Watson, on a scale so large as to excite the admiration of Muschenbroek; who says, in a letter to Watson, 'Magnificentissimis tuis experimentis superasti conatus omnium.' The result was, that the transmission of electricity through a length of 12,000 feet was, to sense, instantaneous,

The essential circumstances of the electric shock were gradually unravelled. Watson found that it did not increase in proportion either to the contents of the phial or the size of the globe by which the electricity was excited; that the outside coating of the glass (which, in the first form of the experiment, was only a film of water,) and its contents, might be varied in different ways. To Franklin is due the merit of clearly pointing out most of the circumstances on which the efficacy of the Leyden phial depends. He showed, in 1747,11 that the inside of the bottle is electrized positively, the outside negatively; and that the shock is produced by the restoration of the equilibrium, when the outside and inside are brought into communication suddenly. But in order to complete this discovery, it remained to be shown that the electric matter was collected entirely at the surface of the glass, and that

Flicher, p. 84.

the opposite electricities on the two opposite sides of the glass were accumulated by their mutual attraction. Monnier the younger discovered that the electricity which bodies can receive, depends upon their surface rather than their mass, and Franklin 12 soon found that the whole force of the bottle, and power of giving a shock, is in the glass itself. This they proved by decanting the water out of an electrized into another bottle, when it appeared that the second bottle did not become electric, but the first remained so. Thus it was found 'that the non-electrics, in contact with the glass, terved only to unite the force of the several parta.'

So far as the effect of the coating of the Leyden phial is concerned, this was satisfactory and complete: but Franklin was not equally successful in tracing the action of the electric matter upon itself, in virtue of which it is accumulated in the phial; indeed, he appears to have ascribed the effect to some property of the The mode of describing this action varied, secondingly as two electric fluids were supposed, (with Dufay,) or one, which was the view taken by Franklin. On this latter supposition the parts of the electric fluid repel each other, and the excess in one surface of the glass expels the fluid from the other surface. This kind of action, however, came into much clearer view in the experiments of Canton, Wilcke, and Æpinus, It was principally manifested in the attractions and repulsions which objects exert when they are in the neighbourhood of electrized bodies; or in the electrical atmosphere, using the phraseology of the time. At present we say that bodies are electrized by induction, when they are thus made electric by the electric attraction and repulsion of other bodies. Canton's experiments were communicated to the Royal Society an 1753, and show that the electricity on each body acts upon the electricity of another body, at a distance, with a repulsive energy. Wilcke, in like manner, showed that parts of non-electrics, plunged in electric atmospheres, acquire an electricity opposite to that of such atmospheres. And Æpinus devised a method of

¹⁷ Letters, Iv. Sect. 16.

examining the nature of the electricity at any part of the surface of a body, by means of which he ascertained its distribution, and found that it agreed with such a law of self-repulsion. His attempt to give mathematical precision to this induction was one of the most important steps towards electrical theory, and must be spoken of shortly, in that point of view. But in the mean time we may observe, that this doctrine was applied to the explanation of the Leyden jar; and the explanation was confirmed by charging a plate of air, and obtaining a shock from it, in a manner which the

theory pointed out.

Before we proceed to the history of the theory, we must mention some other of the laws of phenomena which were noticed, and which theory was expected to explain. Among the most celebrated of these, were the effect of sharp points in conductors, and the phenomena of electricity in the atmosphere. The former of these circumstances was one of the first which Franklin observed as remarkable. It was found that the points of needles and the like throw off and draw off the electric virtue; thus a bodkin, directed towards an electrized ball, at six or eight inches distance, destroyed its electric action. The latter subject, involving the consideration of thunder and lightning, and of many other meteorological phenomena, excited great interest. The comparison of the electric spark to lightning had very early been made; but it was only when the discharge had been rendered more powerful in the Leyden jar, that the comparison of the effects became very plausible. Franklin, about 1750, had offered a few somewhat vague conjectures 18 respecting the existence of electricity in the clouds; but it was not till Wilcke and Æpinus had obtained clear notions of the effect of electric matter at a distance, that the real condition of the clouds could be well understood. In 1752, however, 14 D'Alibard, and other French philosophers, were desirous of verifying Franklin's conjecture of the analogy of thunder and electricity. This they did by erecting a pointed iron rod, forty

⁴ Letter v.

the high, at Marli: the rod was found capable of giving out electrical sparks when a thunder-cloud passed over the place. This was repeated in various parts of Europe, and Franklin suggested that a communication with the clouds might be formed by means of a kite. By these, and similar means, the electricity of the atmosphere was studied by Canton in England, Mazeas in France, Beccaria in Italy, and others elsewhere. These essays soon led to a fatal accident, the death of Richman at Petersburg, while he was, on Aug 6th, 1753, observing the electricity collected from an approaching thunder-cloud, by means of a rod which he called an electrical gnomon: a globe of blue fire was seen to leap from the rod to the head of the unfortunate professor, who was thus struck dead.

[2nd Ed.] [As an important application of the doctrines of electricity, I may mention the contrivances employed to protect ships from the effects of lightning. The use of conductors in such cases is attended with peculiar difficulties. In 1780 the French began to turn their attention to this subject, and Le Roi was ent to Brest and the various sea ports of France for that purpose. Chains temporarily applied in the rigging had been previously suggested, but he endeavoured to place, he says, such conductors in ships as might be fixed and durable. He devised certain long linked rods, which led from a point in the mast-head along a part of the rigging, or in divided stages along the masts, and were fixed to plates of metal in the ship's sides communicating with the sea. But these were either unable to stand the working of the rigging, or otherwise inconvenient, and were finally abandoned.15

The conductor commonly used in the English navy, till recently, consisted of a flexible copper chain, tied, when occasion required, to the mast-head, and reaching down into the sea; a contrivance recommended by Dr. Watson in 1762. But notwithstanding this precaution, the shipping suffered greatly from the effects of lightning.

¹⁵ See Le Roi's Memoir in the Hist, Acad, Sc. for 1790.

Mr. Snow Harris (now Sir William Snow Harris), whose electrical labours are noticed above, proposed to the Admiralty, in 1820, a plan which combined the conditions of ship-conductors, so desirable, yet so difficult to secure: - namely, that they should be permanently fixed, and sufficiently large, and yet should in no way interfere with the motion of the rigging, or with the sliding masts. The method which he proposed was to make the masts themselves conductors of electricity, by incorporating with them, in a peculiar way, two lamins of sheet-copper, uniting these with the metallic masses in the hull by other laming, and giving the whole a free communication with the sea. This method was tried experimentally, . both on models and to a large extent in the navy itself: and a Commission appointed to examine the result reported themselves highly satisfied with Mr. Harris's plan, and strongly recommended that it should be fully carried out in the Navy. 16

apheric electricity any further: and we must now endeavour to see how these phenomena and laws of phenomena which we have related, were worked up into consistent theories; for though many experimental observations and measures were made after this time, they were guided by the theory, and may be considered as having rather discharged the office of confirming

than of suggesting it.

We may observe also that we have now described the period of most extensive activity and interest in electrical researches. These naturally occurred while the general notions and laws of the phenomena were becoming, and were not yet become, fixed and clear. At such a period, a large and popular circle of spectators and amateurs feel themselves nearly upon a level, in the value of their trials and speculations, with more profound thinkers: at a later period, when the subject is become a science, that is, a study in which all must be left far behind who do not come to it with disci-

¹⁶ See Mr. Snow Harris's paper in Phil. Mag. March 1841.

plined, informed, and logical minds, the cultivators are far more few, and the shout of applause less tumultuous and less loud. We may add, too, that the experiments, which are the most striking to the senses, lose much of their impressiveness with their novelty. Electricity, to be now studied rightly, must be reasoned upon mathematically, how slowly such a mode of study makes its way, we shall see in the progress of the

theory, which we must now proceed to narrate.

[2nd Ed.] [A new mode of producing electricity has excited much notice lately. In October, 1840, one of the workmen in attendance upon a boiler belonging to the Newcastle and Durham Railway, reported that the boiler was full of fire; the fact being, that when he placed his hand near it an electrical spark was given out. This drew the attention of Mr. Armstrong and Mr. Pattinson, who made the circumstance publicly known.17 Mr. Armstrong pursued the investigation with great zeal, and after various conjectures was able to announce 18 that the electricity was excited at the point where the steam is subject to friction in its emission. He found too that he could produce a like effect by the emission of condensed air. Following out his views, he was able to construct, for the Polytechnic Institution in London, a 'Hydro-electric Machine,' of greater power than any electrical machine previously made. Dr. Faraday took up the investigation as the subject of the Eighteenth Series of his Researches, sent to the Royal Society, Jan. 26, 1842; and in this he illustrated, with his usual command of copious and luminous experiments, a like view; -that the electricity is produced by the friction of the particles of the water carried along by the stream. And thus this is a new manifestation of that electricity, which, to distinguish it from voltage electricity, is sometimes called Friction Electricity or Muchine Electricity. Dr. Faraday has, however, in the course of this investigation, brought to light several new electrical relations of bodies.

CHAPTER II.

THE PROGRESS OF ELECTRICAL THEORY.

THE cause of electrical phenomena, and the mode of its operation, were naturally at first spoken of in an indistinct and wavering manner. It was called the electric fire, the electric fluid; its effects were attributed to virtues, effluvia, atmospheres. When men's mechanical ideas became somewhat more distinct, the motions and tendencies to motion were ascribed to currents, in the same manner as the cosmical motions had been in the Cartesian system. This doctrine of currents was maintained by Nollet, who ascribed all the phenomena of electrized bodies to the contemporaneous afflux and efflux of electrical matter. It was an important step towards sound theory, to get rid of this notion of moving fluids, and to consider attraction and repulsion as statical forces; and this appears to have been done by others about the same time. Dufay' considered that he had proved the existence of two electricities, the vitreous and the resinous, and conceived each of these to be a fluid which repelled its own parts and attracted those of the other: this is, in fact, the outline of the theory which recently has been considered as the best established; but from various causes it was not at once, or at least, not generally adopted. The hypothesis of the excess and defect of a single fluid is capable of being so treated as to give the same results with the hypothesis of two opposite fluids, and happened to obtain the preference for some time. We have already seen that this hypothesis. according to which electric phenomena arose from the excess and defect of a generally diffused fluid, suggested itself to Watson and Franklin about 1747. Watson found that when an electric body was excited. the electricity was not created, but collected; and Franklin held, that when the Leyden jar was charged.

⁴c. Par. 1733, p. 467.

the quantity of electricity was unaltered, though its distribution was changed. Symmer' maintained the existence of two fluids; and Cigna supplied the main defect which belonged to this tenet in the way in which Dufay held it, by showing that the two opposite electricities were usually produced at the same time. Still the apparent simplicity of the hypothesis of one fluid procured it many supporters. It was that which Franklin adopted, in his explanation of the Leyden experiment; and though, after the first conception of an electrical charge as a disturbance of equilibrium, there was nothing in the development or details of Franklin's views which deserved to win for them any peculiar authority, his reputation, and his skill as a writer, gave a considerable influence to his opinions. Indeed, for a time he was considered, over a large part of Europe, as the creator of the science, and the terms' Franklinism, Franklinist, Franklinian system, occur in almost every page of continental publications on the subject. Yet the electrical phenomena to the knowledge of which Franklin added least, those of induction, were those by which the progress of the theory was most promoted. These, as we have already said, were at first explained by the hypothesis of electrical atmospheres. Lord Mahon wrote a treatise, in which this hypothesis was mathematically treated, yet the hypothesis was very untenable, for it would not account for the most obvious cases of induction, such as the Leyden jar, except the atmosphere was supposed to penetrate glass.

The phenomena of electricity by induction, when fairly considered by a person of clear notions of the relations of space and force, were seen to accommodate themselves very generally to the conception introduced by Dufay; of two electricities each repelling itself and attracting the other. If we suppose that there is only one fluid, which repels itself and attracts all other matter, we obtain, in many cases, the same general

Phil. Trans. 1759. 3 Priestley. p 160. 4 Mém. A. P. 1733, p. 467.

results as if we suppose two fluids; thus, if an electrized body, overcharged with the single fluid, act upon a ball, it drives the electric fluid in the ball to the further side by its repulsion, and then attracts the ball by attracting the matter of the ball more than it repels the fluid which is upon the ball. If we suppose two fluids, the positively electrized body draws the negative fluid to the nearer side of the ball, repels the positive fluid to the opposite side, and attracts the ball on the whole, because the attracted fluid is nearer than that which is repelled. The verification of either of these hypotheses, and the determination of their details, depended necessarily upon experiment and calculation. It was under the hypothesis of a single fluid that this trial was first properly made. Æpinus of Petersburg published, in 1750, his Tentamen Theorie Electricitates et Magnetisma; in which he truces mathematically the consequences of the hypothesis of an electric fluid, attracting all other matter, but repelling itself, the law of force of this repulsion and attraction he did not pretend to assign precisely, confining himself to the supposition that the mutual force of the particles increases as the distance decreases. But it was found, that in order to make this theory tenable, an additional supposition was required, namely, that the particles of bodies repel each other as much as they attract the electric fluid. For if two bodies, A and B, be in their natural electrical condition, they neither attract nor repel each other. Now, in this case, the fluid in A attracts the matter in B and repels the fluid in B with equal energy, and thus no tendency to motion results from the fluid in A; and if we further suppose that the matter in A attracts the fluid in B and repels the matter in B with equal energy, we have the resulting mutual inactivity of the two bodies explained; but without the latter supposition, there would be a mutual attraction; or we may put the truth more simply thus, two negatively electrized bodies repel each other; if negative electrization were merely the abstraction of the fluid

⁶ Robison, vol. iv p 18

which is the repulsive element, this result could not follow except there were a repulsion in the bodies themselves, independent of the fluid. And thus Epinus found himself compelled to assume this mutual repulsion of material particles; he had, in fact, the alternative of this supposition, or that of two fluids, to choose between, for the mathematical results of both hypotheses are the same. Wilcke, a Swede, who had at first asserted and worked out the Æpinian theory in its original form, afterwards inclined to the opinion of Symmer; and Coulomb, when, at a later period, he confirmed the theory by his experiments and determined the law of force, did not hesitate to prefer⁶ the theory of two fluids, 'because,' he says, 'it appears to me contradictory to admit at the same time, in the particles of bodies, an attractive force in the inverse ratio of the squares of the distances, which is demonstrated by universal gravitation, and a repulsive force in the same inverse ratio of the squares of the distances, a force which would necessarily be infinitely great relatively to the action of gravitation.' We may add, that by forcing us upon this doctrine of the universal repuision of matter, the theory of a single fluid seems quite to lose that superiority in the way of simplicity which had originally been its principal recommendation.

The mathematical results of the supposition of Epinus, which are, as Coulomb observes, the same as of that of the two fluids, were traced by the author himself, in the work referred to, and shown to agree, in a great number of cases, with the observed facts of electrical induction, attraction, and repulsion. Apparently this work did not make its way very rapidly through Europe; for in 1771, Henry Cavendish stated the same hypothesis in a paper read before the Royal Society; which he prefaces by saying, 'Since I first wrote the following paper, I find that this way of accounting for the phenomena of electricity is not new.

6 Mem Ac. P 1788, p. 671.

Æpinus, in his Tentamen Theoriæ Electricitatis et Magnetismi, has made use of the same or nearly the same hypothesis that I have; and the conclusions he draws from it agree nearly with mine as far as he goes."

The confirmation of the theory was, of course, to be found in the agreement of its results with experiment; and in particular, in the facts of electrical induction, attraction, and repulsion, which suggested the theory. Æpinus showed that such a confirmation appeared in a number of the most obvious cases; and to these, Cavendish added others, which, though not obvious, were of such a nature that the calculations, in general difficult or impossible, could in these instances be easily performed; as, for example, cases in which there are plates or globes at the two extremities of a long wire. In all these cases of electrical action, the theory was justified. But in order to give it full confirmation, it was to be considered whether any other facts, not immediately assumed in the foundation of the theory, were explained by it; a circumstance which, as we have seen, gave the final stamp of truth to the theories of astronomy and optics. Now we appear to have such confirmation, in the effect of points, and in the phenomena of the electrical discharge. The theory of neither of these was fully understood by Cavendish, but he made an approach to the true view of them. If one part of a conducting body be a sphere of small radius, the electric fluid upon the surface of this sphere will, it appears by calculation, be more dense, and tend to escape more energetically, in proportion as the radius of the sphere is smaller; and, therefore, if we consider a point as part of the surface of a sphere of imperceptible radius, it follows from the theory that the effort of the fluid to escape at that place will be enormous; so that it may easily be supposed to overcome the resisting causes. And the discharge may be explained in nearly the same manner; for when a conductor is brought nearer and nearer to an electrized body, the opposite electricity is more and more accumulated by attraction on the side next to the electrized body, its tension becomes greater by the increase of its

quantity and the diminution of the distance, and at last it is too strong to be contained, and leaps out in

the form of a spark.

The light, sound, and mechanical effects produced by the electric discharge, made the electric fluid to be not merely considered as a mathematical hypothesis, useful for reducing phenomena to formulæ (as for a long time the magnetic fluid was), but caused it to be at once and universally accepted as a physical reality, of which we learn the existence by the common use of the senses, and of which measures and calculations

are only wanted to teach us the laws.

The applications of the theory of electricity which I have principally considered above, are those which belong to conductors, in which the electric fluid is perfectly moveable, and can take that distribution which the forces require. In non-conducting or electric bodies, the conditions to which the fluid is subject are less easy to determine, but by supposing that the fluid moves with great difficulty among the particles of such bodies,—that nevertheless it may be dislodged and accumulated in parts of the surface of such bodies, by friction and other modes of excitement; and that the earth is an inexhaustible reservoir of electric matter,—the principal facts of excitation and the like receive a tolerably satisfactory explanation.

The theory of Æpinus, however, still required to have the law of action of the particles of the fluid determined. If we were to call to mind how momentous an event in physical astronomy was the determination of the law of the cosmical forces, the inverse aquare of the distance, and were to suppose the importance and difficulty of the analogous step in this case to be of the same kind, this would be to mistake the condition of science at that time. The leading idea, the conception of the possibility of explaining natural phenomena by means of the action of forces, on rigorously mechanical principles, had already been promulgated by Newton, and was, from the first, seen to be peculiarly applicable to electrical phenomena; so that the very material step of clearly proposing the problem,

often more important than the solution of it, had already been made. Moreover the confirmation of the truth of the assumed cause in the astronomical case depended on taking the right law; but the electrical theory could be confirmed, in a general manner at least, without this restriction. Still it was an important discovery that the law of the inverse square prevailed in these as well as in cosmical attractions.

It was impossible not to conjecture beforehand that it would be so. Cavendish had professed in his calculations not to take the exponent of the inverse power, on which the force depended, to be strictly 2, but to leave it indeterminate between I and 3; but in his applications of his results, he obviously inclines to the assumption that it is 2. Experimenters tried to establish this in various ways. Robison,9 in 1769, had already proved that the law of force is very nearly or exactly the inverse square; and Mayer 10 had discovered, but not published, the same result. The clear and satisfactory establishment of this truth is due to Coulomb, and was one of the first steps in his important series of researches on this subject. In his first paper 11 in the Memoirs of the Academy for 1785. he proves this law for small globes; in his second Memoir he shows it to be true for globes one and two feet in diameter. His invention of the torsion-balance, which measures very small forces with great certainty and exactness, enabled him to set this question at rest for ever.

The law of force being determined for the particles of the electric fluid, it now came to be the business of the experimenter and the mathematician to compare the results of the theory in detail with those of experimental measures. Coulomb undertook both portions of the task. He examined the electricity of portions of bodies by means of a little disk (his tangent plane) which he applied to them and then removed, and which thus acted as a sort of electric taster. His numerical

^{*} Works, iv. p. 58 10 Blog. Univ art Coulomb, by Blot. 11 Min. A. P. 1785, pp. 569, 578.

results (the intensity being still measured by the torsion-balance) are the fundamental facts of the theory of the electrical fluid. Without entering into detail, we may observe that he found the electricity to be entirely collected at the surface of conductors (which Beccaria had before shown to be the case), and that he examined and recorded the electric intensity at the surface of globes, cylinders, and other conducting bodies, placed within each other's influence in various

WAVE

The mathematical calculation of the distribution of two fluids, all the particles of which attract and repol each other according to the above law, was a problem of no ordinary difficulty; as may easily be imagined, when it is recollected that the attraction and repulsion determine the distribution, and the distribution reciprocally determines the attraction and repulsion. The problem was of the same nature as that of the figure of the earth; and its rigorous solution was beyond the powers of the analysis of Coulomb's time. He obtained, however, approximate solutions with much ingenuity; for instance, in a case in which it was obvious that the electric fluid would be most accumulated at and near the equator of a certain sphere, he calculated the action of the sphere on two suppositions: first, that the luid was all collected precisely at the equator; and next, that it was uniformly diffused over the surface; and he then assumed the actual case to be intermediate between these two. By such artifices he was able to show that the results of his experiments and of his calculations gave an agreement sufficiently near to entitle him to consider the theory as established on a solid basis.

Thus, at this period, mathematics was behind experiment; and a problem was proposed, in which theoretical numerical results were wanted for comparison with observation, but could not be accurately obtained, as was the case in astronomy also, till the time of the approximate solution of the Problem of Three Bodies, and the consequent formation of the Tables of the Moon and Planets on the theory of universal gravita-

tion. After some time, electrical theory was relieved from this reproach, mainly in consequence of the progress which astronomy had occasioned in pure mathematics. About 1801, there appeared in the Bulletin des Sciences, 19 an exact solution of the problem of the distribution of electric fluid on a spheroid, obtained by M. Biot, by the application of the peculiar methods which Laplace had invented for the problem of the figure of the planets. And in 1811, M. Poisson applied Laplace's artifices to the case of two spheres acting upon one another in contact, a case to which many of Coulomb's experiments were referrible, and the agreement of the results of theory and observation, thus extricated from Coulomb's numbers, obtained above forty years previously, was very striking and convincing.18 It followed also from Poisson's calculations, that when two electrized spheres are brought near each other, the accumulation of the opposite electricities on their nearest points increases without limit as the spheres approach to contact; so that before the contact takes place, the external resistance will be overcome, and a spark will pass.

Though the relations of non-conductors to electricity, and various other circumstances, leave many facts imperfectly explained by the theory, yet we may venture to say that, as a theory which gives the laws of the phenomena, and which determines the distribution of those elementary forces, on the surface of electrized bodies, from which elementary forces (whether arising from the presence of a fluid or not,) the total effects result, the doctrine of Dufay and Coulomb, as developed in the analysis of Poisson, is securely and permanently established. This part of the subject has been called statical electricity. In the establishment of the theory of this branch of science, we must, I conceive, allow to Dufay more merit than is generally ascribed to him; since he saw clearly, and enunciated in a manner which showed that he duly appreciated their capital character, the two chief principles,—the con-

ditions of electrical attraction and repulsion, and the apparent existence of two kinds of electricity. His views of attraction are, indeed, partly expressed in terms of the Cartesian hypothesis of vortices, then prevalent in France; but, at the time when he wrote, these forms of speech indicated scarcely anything besides the power of attraction. Franklin's real ment as a discoverer was, that he was one of the first who distinctly concerved the electrical charge as a derangement of equilibrium. The great fame which, in his day, be enjoyed, arose from the clearness and spirit with which he narrated his discoveries; from his dealing with electricity in the imposing form of thunder and lightning; and partly, perhaps, from his character as an American and a politician, for he was already, in 1736, engaged in public affairs as clerk to the General Assembly of Pennsylvania, though it was not till a later period of his life that his admirers had the occasion of saying of him -

Eripait oulis fulmen sceptrumque tyrannis;

Born to control all lawless force, all herce and baleful away, The thunder's bolt, the tyrant's rod, altho he wrenched away.

Æpinus and Coulomb were two of the most emment physical philosophers of the last century, and laboured in the way peculiarly required by that generation; whose office it was to examine the results, in particular subjects, of the general conception of attraction and repulsion, as introduced by Newton. The reasonings of the Newtonian period had, in some measure, anticipated all possible theories resembling the electrical doctrine of Epinus and Coulomb, and, on that account, this doctrine could not be introduced and confirmed in a sudden and striking manner, so as to make a great epoch. Accordingly, Dufay, Symmer, Watson, Franklin, Apinus and Coulomb, have all a share in the process ot induction. With reference to these founders of the theory of electricity, Poisson holds the same place which Laplace holds with reference to Newton.

The reception of the Coulombian theory (so we must call it, for the Æpinian theory implies lonly,)

has hitherto not been so general as might have been reasonably expected from its very beautiful accordance with the facts which it contemplates. This has partly been owing to the extreme abstruseness of the mathematical reasoning which it employs, and which put it out of the reach of most experimenters and writers of works of general circulation. The theory of Æpinus was explained by Robison in the Encyclopædia Britannica; the analysis of Poisson has recently been presented to the public in the Encyclopædia Metropolitana, but is of a kind not easily mastered even by most mathematicians. On these accounts probably it is, that in English compilations of science, we find, even to this day, the two theories of one and of two fluids stated as if they were nearly on a par in respect of their experimental evidence. Still we may say that the Coulombian theory is probably assented to by all who have examined it, at least as giving the laws of phenomena; and I have not heard of any denial of it from such a quarter, or of any attempt to show it to be erroneous by detailed and measured experiments. Mr. Snow Harris has recently described some important experiments and measures; but his apparatus was of such a kind that the comparison of the results with the Coulombian theory was not easy; and indeed the mathematical problems which Mr. Harris's combinations offered, require another Poisson for their solution. Still the more obvious results are such as agree with the theory, even in the cases in which their author considered them to be inexplicable. For example, he found that by doubling the quantity of electricity of a conductor, it attracted a body with four times the force; but the body not being insulated, would have its electricity also doubled by induction, and thus the fact was what the theory required.

Though it is thus highly probable that the Coulombian theory of electricity (or the Æpinian, which is mathematically equivalent) will stand as a true representation of the law of the elementary actions, we must

¹¹ Phil. Trans. 1834, P. 2.

vet allow that it has not received that complete evidence. by means of experiments and calculations added to those of its founders, which the precedents of other permanent sciences have led us to look for. The experiments of Coulomb, which he used in the establishment of the theory, were not very numerous, and they were limited to a peculiar form of bodies, namely spheres. In order to form the proper sequel to the promulgation of this theory, to give a full confirmation, and to ensure its general reception, we ought to have experiments more numerous and more varied (such as those of Mr. Harris are) shown to agree in all respects with results calculated from the theory. This would, as we have said, be a task of labour and difficulty; but the person who shall execute it will deserve to be considered as one of the real founders of the true doctrine of electricity. To show that the coincidence between theory and observation, which has already been proved for spherical conductors, obtains also for bodies of other forms, will be a step in electricity analogous to what was done in astronomy, when it was shown that the law of gravitation applied to comets as well as to planets.

But although we consider the views of Æpinus or Coulomb in a very high degree probable as a formal theory, the question is very different when we come to examine them as a physical theory;—that is, when we inquire whether there really is a material electric fluid

or fluids.

Question of One or Two Fluids.—In the first place as to the question whether the fluids are one or two;—Coulomb's introduction of the hypothesis of two fluids has been spoken of as a reform of the theory of Æpinus; it would probably have been more safe to have called his labours an advance in the calculation, and in the comparison of hypothesis with experiment, than to have used language which implied that the question, between the rival hypotheses of one or two fluids, could be treated as settled. For, in reality, if we assume, as Æpinus does, the mutual repulsion of all the particles of matter, in addition to the repulsion of

the particles of the electric fluid for one another and their attraction for the particles of matter, the one fluid of Æpinus will give exactly the same results as the two fluids of Coulomb. The mathematical formulæ of Coulomb and of Poisson express the conditions of the one case as well as of the other; the interpretation only being somewhat different. The place of the forces of the resinous fluid is supplied by the excess of the forces ascribed to the matter above the forces of the fluid, in the parts where the electric fluid is deficient.

The obvious argument against this hypothesis is, that we ascribe to the particles of matter a mutual repulsion, in addition to the mutual attraction of universal gravitation, and that this appears incongruous. Accordingly, Æpinus says, that when he was first driven to this proposition it horrified him. 15 But we may answer it in this way very satisfactorily:-It we suppose the mutual repulsion of matter to be somewhat less than the mutual attraction of matter and electric fluid, it will follow, as a consequence of the hypothesis, that besides all obvious electrical action, the particles of matter would attract each other with forces varying inversely as the square of the distance. Thus gravitation itself becomes an electrical phenomenon. arising from the residual excess of attraction over repulsion; and the fact which is urged against the hypothesis becomes a confirmation of it. By this consideration the prerogative of simplicity passes over to the side of the hypothesis of one fluid; and the rival view appears to lose at least all its superiority.

Very recently, M. Mosotti 16 has calculated the results of the Æpinian theory in a far more complete manner than had previously been performed; using Laplace's coefficients, as Poisson had done for the Coulombian theory. He finds that, from the supposition of a fluid and of particles of matter exercising such forces as that

¹⁶ Neque diffiteor cum ipsu se 16 Sur les Forces qui régissent mihi offerret . . me ad ipsum la Constitution Intérieure des quodammodo exhorrulese, Tenta-Corps. Turin. 1836.

men Theor. Elect. p. 39.

theory assumes (with the very allowable additional supposition that the particles are small compared with their distances), it follows that the particles would exert a force, repulsive at the smallest distances, a little further on vanishing, afterwards attractive, and at all sensible distances attracting in proportion to the inverse square of the distance. Thus there would be a position of stable equilibrium for the particles at a very small distance from each other, which may be, M. Mosotti suggests, that equilibrium on which their physical structure depends. According to this view, the resistance of bodies to compression and to extension. well as the phenomena of statical electricity and the mutual gravitation of matter, are accounted for by the same hypothesis of a single fluid or ether. theory which offers a prospect of such a generalization is worth attention; but a very clear and comprehensive view of the doctrines of several sciences is requisite to prepare us to estimate its value and probable success.

Question of the Material Reality of the Electric Pluid -At first sight, the beautiful accordance of the experiments with calculations founded upon the attractions and repulsions of the two hypothetical fluids, persuade us that the hypothesis must be the real state of things. But we have already learned that we must not trust such evidence too readily. It is a curious instance of the mutual influence of the histories of two provinces of science, but I think it will be allowed to be just, to say that the discovery of the polarization of heat has done much to shake the theory of the electric fluids as a physical reality. For the doctrine of a material caloric appeared to be proved (from the laws of conduction and radiation) by the same kind of mathematical evidence (the agreement of the laws respecting the elementary actions with those of fluids), which we have for the doctrine of material electricity. Yet we now seem to see that heat cannot be matter, since its rays have sides, in a manner in which a stream of particles of matter cannot have sides, without inadmusible hypotheses. We see, then, that it will not be contrary to precedent, if our electrical theory, representing with perfect accuracy the laws of the actions, in all their forms, simple and complex, should yet be fallacious as a view of the cause of the actions.

Any true view of electricity must include, or at least be consistent with, the other classes of the phenomena, as well as this statical electrical action; such as the conditions of excitation and retention of electricity: to which we may add, the connexion of electricity with magnetism and with chemistry;—a vast field, as yet dimly seen. Now, even with regard to the simplest of these questions, the cause of the retention of electricity at the surface of bodies, it appears to be impossible to maintain Coulomb's opinion, that this is effected by the resistance of air to the passage of electricity. The other questions are such as Coulomb did not attempt to touch; they refer, indeed, principally to laws not suspected at his time. How wide and profound a theory must be which deals worthily with these, we shall obtain some indications in the succeeding part of our history.

But it may be said on the other side, that we have the evidence of our senses for the reality of an electric fluid :- we see it in the spark; we hear it in the explosion; we feel it in the shock; and it produces the effects of mechanical violence, piercing and tearing the bodies through which it passes. And those who are disposed to assert a real fluid on such grounds, may appear to be justified in doing so, by one of Newton's 'Rules of Philosophizing,' in which he directs the philosopher to assume, in his theories, 'causes which are true.' The usual interpretation of a 'vers causa, has been, that it implies causes which, independently of theoretical calculations, are known to exist by their mechanical effects; as gravity was familiarly known to exist on the earth, before it was extended to the heavers. The electric fluid might seem to be

such a vera causa.

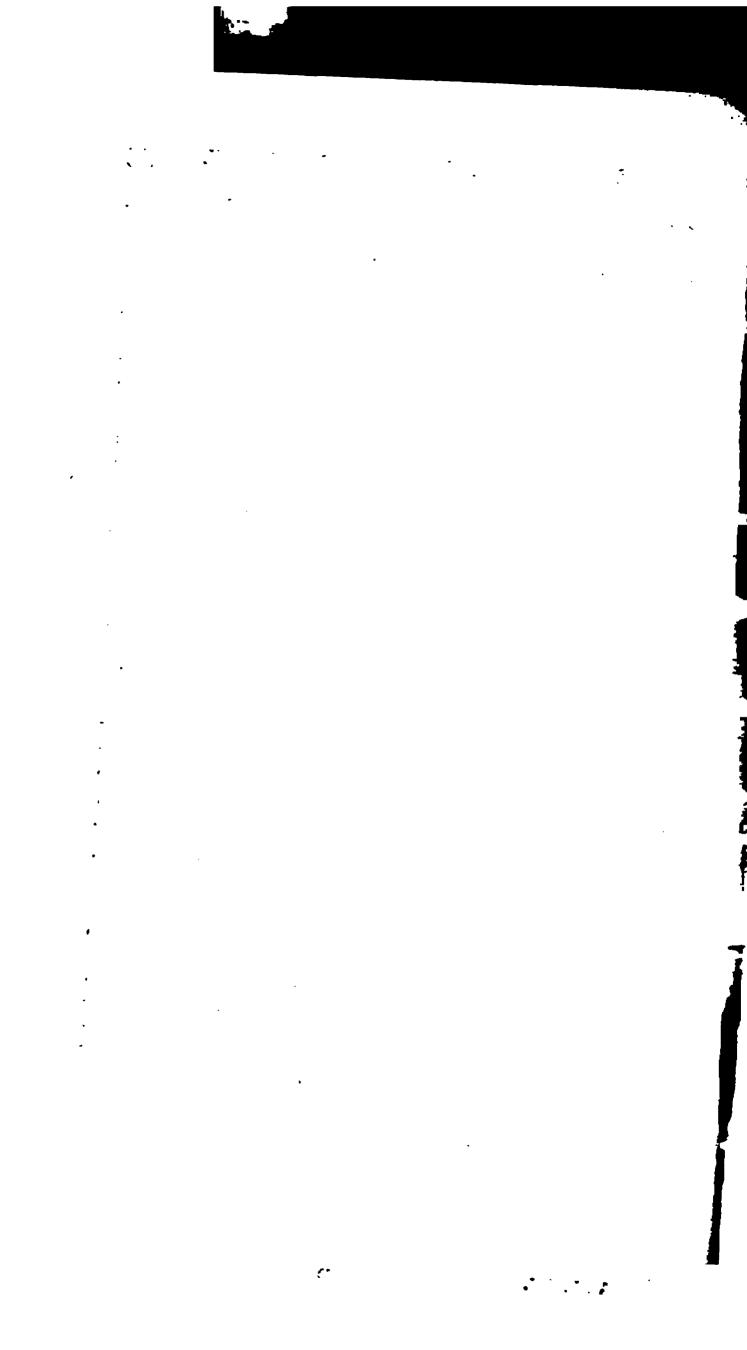

To this I should venture to reply, that this reasoning shows how delusive the Newtonian rule, so interpreted, may be. For a moment's consideration will satisfy us that none of the circumstances, above adduced,

can really prove material currents, rather than vibrations, or other modes of agency. The spark and shock are quite insufficient to supply such a proof. Sound is vibrations,-hight is vibrations; vibrations may affect our nerves, and may rend a body, as when glasses are broken by sounds. Therefore all these supposed indications of the reality of the electric fluid are utterly fallacious. In truth, this mode of applying Newton's rule consists in elevating our first rude and unscientific impressions into a supremacy over the results of calculation, generalization, and systematic induction. 16

Thus our conclusion with regard to this subject is, that if we wish to form a stable physical theory of electricity, we must take into account, not only the laws of statical electricity, which we have been chiefly considering, but the laws of other kinds of agency, different from the electric, yet connected with it. For the electricity of which we have hitherto spoken, and which is commonly excited by friction, is identical with valvanic action, which is a result of chemical combinations, and belongs to chemical philosophy. The connexion of these different kinds of electricity with one another leads us into a new domain; but we must, in the first place, consider their mechanical laws. We now proceed to another branch of the same subject, Magnetism.

HISTORY OF MAGNETISM.

Brytcz, ut interes fera munera militia?
Per maria ac terras omneis sopita quiescant.
Nam tu sola potes tranquilla pace juvare
Mortales, quoniam belli fera munera Mavors
Armipotens regit, in gremium qui sepe tuum so
Rejicit, seterno devictus vulnere amoris;
Atque ita suspiciens tereti cervice reposta,
Pascit amore avidos inhians in te, Dea, visus,
Eque tuo pendet resupini spiritus ore.
Hunc tu, Diva, tuo recubantem corpore sancto
Circumfusa super, sunves ex ore loquelas
Funde, petens placidam Romanis, incluta, pacem.

LUCRET. L 31.

O charming Goddesa, whose mysterious sway, The unseen hosts of earth and sky obey; To whom, though cold and hard to all besides, The Iron God by strong affection glides, Flings himself eager to thy close embrace, And bends his head to gaze upon thy face; Do thou, what time thy foulding arms are thrown Around his form, and he is all thy own, Do thou, thy Rome to save, thy power to prove, Beg him to grant a boon for thy dear love : Beg him no more in battle-fields to deal, Or crush the nations with his mailed heel. But, touched and softened by a worthy flame, Quit sword and spear, and seek a better fame. Bid him to make all war and slaughter cease. And ply his genuine task in arts of peace: And by thee guided o'er the trackless surge. Bear wealth and joy to ocean's farthest verge.

CHAPTER I.

DISCOVERY OF LAWS OF MAGNETIC PHENOMENA.

THE history of Magnetism is in a great degree similar to that of Electricity, and many of the same persons were employed in the two trains of research. The general fact, that the magnet attracts iron, was nearly al! that was known to the ancients, and is frequently mentioned and referred to; for instance, by Pliny, who wonders and declaims concerning it, in his usual exaggerated style.1 The writers of the Stationary Period, in this subject as in others, employed themselves in collecting and adorning a number of extravagant tales, which the slightest reference to experiment would have disproved; as, for example, that a magnet when it has lost its virtue, has it restored by goat's blood. Gilbert, whose work De Magnete we have already mentioned, speaks with becoming indignation and pity of this bookish folly, and repeatedly asserts the paramount value of experimenta. He himself, no doubt, acted up to his own precepts; for his work contains all the fundamental facts of the science, so fully examined indeed, that even at this day we have little to add to them. Thus, in his first Book, the subjects of the third, fourth, and fifth Chapters are,—that the magnet has poles,—that we may call these poles the north and the south pole, —that in two magnets the north pole of each attracts the south pole and repels the north pole of the other. This is, indeed, the cardinal fact on which our generalizations rest, and the reader will perceive at once its resemblance to the leading phenomena of statical electricity.

But the doctrines of magnetism, like those of heat, have an additional claim on our notice from the manner

¹ Higt. Nat. 11b. xxxvi. 0, 25.

in which they are exemplified in the globe of the earth. The subject of terrestrial magnetism forms a very important addition to the general facts of magnetic attraction and repulsion. The property of the magnet by which it directs its poles exactly or nearly north and south, when once discovered, was of immense importance to the mariner. It does not appear easy to trace with certainty the period of this discovery. Passing over certain legends of the Chinese, as at any rate not bearing upon the progress of European science, the earliest notice of this property appears to be contained in the Poem of Guyot de Provence, who describes the needle as being magnetized, and then placed in or on a straw, (floating on water, as I presume:)

Puis se torne la pointe toute Contre l'estoile sans doute;

that is, it turns towards the pole-star. This account would make the knowledge of this property in Europe anterior to 1200. It was afterwards found that the needle does not point exactly towards the north, Gilbert was aware of this deviation, which he calls the variation, and also, that it is different in different places.4 He maintained on theoretical principles also, that at the same place the variation is constant; probably in his time there were not any recorded observations by which the truth of this assertion could be tested; it was afterwards found to be false. The alteration of the variation in proceeding from one place to another was, it will be recollected, one of the circumstances which most alarmed the companions of Columbus in 1492. Gilbert says, 6 'Other learned men have, in long navigations, observed the differences of magnetic variation, as Thomas Hariot, Robert Hues, Edward Wright, Abraham Kendall, all Englishmen: others have invented magnetic instruments and con-

venient modes of observation, such as are requisite for those who take long voyages, as William Borough in his book concerning the variation of the compass, William Barlo in his supplement, William Norman in his New Attractive. This is that Robert Norman (a good seaman and an ingenious artificer,) who first discovered the dip of magnetic iron.' This important discovery was made? in 1576. From the time when the difference of the variation of the compass in different places became known, it was important to mariners to register the variation in all parts of the world. Halley was appointed to the command of a ship in the Royal Navy by the Government of William and Mary, with orders 'to seek by observation the discovery of the rule for the variation of the compass.' He published Magnetic Charts, which have been since corrected and improved by various persons. The most recent are those of Mr. Yates in 1817, and of M. Hansteen. The dip, as well as the variation, was found to be different in different places. M. Humboldt, in the course of his travels, collected many such observations. And both the observations of variation and of dip seemed to indicate that the earth, as to its effect on the magnetic needle, may, approximately at least, be considered as a magnet, the poles of which are not far removed from the earth's poles of rotation. Thus we have a magnetic equator, in which the needle has no dip, and which does not deviate far from the earth's equator; although, from the best observations, it appears to be by no means a regular circle. And the phenomena, both of the dip and of the variation, in high northern latitudes, appear to indicate the existence of a pole below the surface of the earth to the north of Hudson's Bay. In his second remarkable expedition into those regions, Captain Ross is supposed to have reached the place of this pole, the dipping-needle there pointing vertically downwards, and the variation-compass turning towards this point in the adjacent regions. We shall hereafter have to consider the more complete and connected views which have been taken of terrestrial magnetism.

In 1633, Gellibrand discovered that the variation is not constant, as Gilbert imagined, but that at London it had diminished from eleven degrees east in 1580, to four degrees in 1633. Since that time the variation has become more and more westerly; it is now about twenty-five degrees west, and the needle is supposed to

have begun to travel eastward again.

The next important fact which appeared with respect to terrestrial magnetism was, that the position of the needle is subject to a small diurnal variation: this was discovered in 1722, by Graham, a philosophical instrument-maker, of London. The daily variation was established by one thousand observations of Graham, and confirmed by four thousand more made by Canton, and is now considered to be out of dispute. It appeared also, by Canton's researches, that the diurnal variation undergoes an annual inequality, being nearly a quarter of a degree in June and July, and only half

that quantity in December and January.

Having thus noticed the principal facts which belong to terrestrial magnetism, we must return to the consideration of those phenomena which gradually led to a consistent magnetic theory. Gilbert observed that both smelted iron and hammered iron have the magnetic virtue, though in a weaker degree than the magnet itself,8 and he asserted distinctly that the magnet is merely an ore of iron, (lib. i. c. 16, Quod magnes et vena ferri idem sunt.) He also noted the increased energy which magnets acquire by being armed; that is, fitted with a cap of polished iron at each pole.9 But we do not find till a later period any notice of the distinction which exists between the magnetical properties of soft iron and of hard steel; the latter being susceptible of being formed into artificial magnets, with permanent poles; while soft iron is only passively magnetic, receiving a temporary polarity from the action of a magnet near 2 but being the property when the market is removed. A sent the middle of the last century, further necessary to the of making artificial magnetic visits expensed in page all magnetic bolics provided in the way.

The remaining experience which the theory that they will be best considered along with it, said to their Therefore we now proceed.

CHAPTER IL

PROGRESS OF MAGNETIC THEORY.

THEORY of Magnetic Action.—The assumption of a fluid, as a mode of explaining the phenomena, was far less obvious in magnetic than in electric cases, yet it was soon arrived at. After the usual philosophy of the middle ages, the 'forms' of Aquinas, the 'efflux' of Cusanus, the 'vapours' of Costæus, and the like, which are recorded by Gilbert, we have his own theory, which he also expresses by ascribing the effects to a 'formal efficiency;'—a 'form of primary globes; the proper entity and existence of their homogeneous parts, which we may call a primary and radical and astral form:'—of which forms there is one in the sun, one in the moon, one in the earth, the latter being the magnetic virtue.

Without attempting to analyse the precise import of these expressions, we may proceed to Descartes's explanation of magnetic phenomena. The mode in which he presents this subject? is, perhaps, the most persuasive of his physical attempts. If a magnet be placed among iron filings, these arrange themselves in curve lines, which proceed from one pole of the magnet to the other. It was not difficult to conceive these to be the traces of currents of ethercal matter which circulate through the magnet, and which are thus rendered sensible even to the eye. When phenomena could not be explained by means of one vortex, several were introduced. Three Memoirs on Magnetism, written on such principles, had the prize adjudged? by

the French Academy of Sciences in 1746.

But the Cartesian philosophy gradually declined; and it was not difficult to show that the magnetic curves, as well as other phenomena, would, in fact,

Gilb. lib. il c. 3, 4. 2 Prin Phil. pars c. iv 146.

2 Coulomb, 1789, p. 484.

result from the attraction and repulsion of two poles. The analogy of magnetism with electricity was so strong and clear, that similar theories were naturally proposed for the two sets of facts, the distinction of bodies into conductors and electrics in the one case, corresponding to the distinction of soft iron and hard steel, in their relations to magnetism. . Epinus published a theory of magnetism and electricity at the same time (1759); and the former theory, like the latter, explained the phenomena of the opposite poles as results of the excess and defect of a magnetic 'fluid,' which was dislodged and accumulated in the ends of the body, by the repulsion of its own particles, and by the attraction of iron or steel, as in the case of induced electricity. The Æpinian theory of magnetism, as of electricity, was recast by Coulomb, and presented in a new shape, with two fluids instead of one. But before this theory was reduced to calculation, it was obviously desirable, in the first place, to determine the law of orce.

In magnetic, as in electric action, the determination of the law of attraction of the particles was attended at first with some difficulty, because the action which a finite magnet exerts is a compound result of the attractions and repulsions of many points. Newton had imagined the attractive force of magnetism to be inversely as the cube of the distance; but Mayer in 1760, and Lambert a few years later, asserted the law to be, in this as in other forces, the inverse square. Coulomb has the ment of having first clearly confirmed this law, by the use of his torsion balance. He established, at the same time, other very important facts, for instance, 'that the directive magnetic force, which the earth exerts upon a needle, is a constant quantity, parallel to the magnetic meridian, and passing through the same point of the needle whatever be its position.' This was the more important, because it was necessary, in the first place, to allow for the effect of the terrestrial force, before the mutual action of the magnets

⁴ Mem. A. P. 1784, ad Mem. p. 593.

could be extricated from the phenomena. Coulomb then proceeded to correct the theory of magnetism.

Coulomb's reform of the Æpinian theory, in the case of magnetism, as in that of electricity, substituted two fluids (an austral and a boreal fluid,) for the single fluid; and in this way removed the necessity under which Æpinus found himself, of supposing all the particles of iron and steel and other magnetic bodies to have a peculiar repulsion for each other, exactly equal to their attraction for the magnetic fluid. in the case of magnetism, another modification was necessary. It was impossible to suppose here, as in the electrical phenomena, that one of the fluids was accumulated on one extremity of a body, and the other fluid on the other extremity; for though this might appear, at first sight, to be the case in a magnetic needle, it was found that when the needle was cut into two halves, the half in which the austral fluid had seemed to predominate, acquired immediately a boreal pole opposite to its austral pole, and a similar effect followed in the other half. The same is true, into however many parts the magnetic body be cut. The way in which Coulomb modified the theory so as to reconcile it with such facts, is simple and satisfactory. He supposes the magnetic body to be made up of 'molecules or integral parts,' or, as they were afterwards called by M. Poisson, 'magnetic elements.' In each of these elements, (which are extremely minute,) the fluids can be separated, so that each element has an austral and a boreal pole; but the austral pole of an element which is adjacent to the boreal pole of the next, neutralizes, or nearly neutralizes, its effect; so that the sensible magnetism appears only towards the extremities of the body, as it would do if the fluids could permeate the body freely. We shall have exactly the same result, as to sensible magnetic force, on the one supposition and on the other, as Coulomb showed.?

The theory, thus freed from manifest incongruities,

⁵ p. 603.
6 Mem. A. P. 1789, p. 488.
7 Mem. A. P. p. 493.

was to be reduced to calculation, and compared with theory; this was done in Coulomb's Seventh Memoir. The difficulties of calculation in this, as in the electric problem, could not be entirely surmounted by the analysis of Coulomb; but by various artifices, he obtained theoretically the relative amount of magnetism at several points of a needle, and the proposition that the directive force of the earth on similar needles saturated with magnetism, was as the cube of their dimensions; conclusions which agreed with experiment.

The agreement thus obtained was sufficient to give a great probability to the theory; but an improvement of the methods of calculation, and a repetition of experiments, was, in this as in other cases, desirable, as a confirmation of the labours of the original theorist. These requisites, in the course of time, were supplied. The researches of Laplace and Legendre on the figure of the earth had (as we have already stated,) introduced some very peculiar analytical artifices, applicable to the attractions of spheroids; and these methods were employed by M. Biot in 1811, to show that on an elliptical spheroid, the thickness of the fluid in the direction of the radius would be as the distance from the center. 10 But the subject was taken up in a more complete manner in 1824 by M. Poisson, who obtained general expressions for the attractions or repulsions of a body of any form whatever, magnetized by influence, upon a given point; and in the case of spherical bodies was able completely to solve the equations which determine these forces. 11

Previously to these theoretical investigations, Mr. Barlow had made a series of experiments on the effect of an iron sphere upon a compass needle; and had obtained empirical formulæ for the amount of the deviation of the needle, according to its dependence upon the position and magnitude of the sphere. He afterwards deduced the same formulæ from a theory

⁹ A. P. 1789. ⁹ p. 485. ¹⁰ Bull. der Sc. No. li.

which was, in fact, identical with that of Coulomb, but which he considered as different, in that it supposed the magnetic fluids to be entirely collected at the surface of the sphere. He had indeed found, by experiment, that the surface was the only part in which there was any sensible magnetism; and that a thin shell of iron would produce the same effect as a solid ball of the same diameter.

But this was, in fact, a most complete verification of Coulomb's theory. For though that theory did not suppose the magnetism to be collected solely at the surface, as Mr. Barlow found it, it followed from the theory, that the sensible magnetic intensity assumed the same distribution, (namely, a surface distribution,) as if the fluids could permeate the whole body, instead of the 'magnetic elements' only. Coulomb, indeed, had not expressly noticed the result, that the sensible magnetism would be confined to the surface of bodies; but he had found that, in a long needle, the magnetic fluid might be supposed to be concentrated very near the extremities, just as it is in a long electric body. The theoretical confirmation of this rule among the other consequences of the theory,-that the sensible magnetism would be collected at the surface, - was one of the results of Poisson's analysis. For it appeared that if the sum of the electric elements of the body was equal to the whole body, there would be no difference between the action of a solid sphere and a very thin shell.

We may, then, consider the Coulombian theory to be fully established and verified, as a representation of the laws of magnetical phenomena. We may add, as a remarkable and valuable example of an ulterior step in the course of sciences, the application of the laws of the distribution of magnetism to the purposes of navigation. It had been found that the mass of iron which exists in a ship produces a deviation in the direction of the compass needle, which was termed 'local attraction,' and which rendered the compass an erroneous guide. Mr. Barlow proposed to correct this by a plate of iron placed near the compass; the plate being of comparatively small mass, but, in consequence of its

expanded form, and its proximity to the needle, of

equivalent effect to the disturbing cause.

[2nd Ed.] [This proposed arrangement was not successful, because as the ship turns into different positions, it may be considered as revolving round a vertical axis; and as this does not coincide with the magnetic axis, the relative magnetic position of the disturbing parts of the ship, and of the correcting plate, will be altered so that they will not continue to counteract each other. In high magnetic latitudes the correcting plate was used with success.

But when iron ships became common, a correction of the effect of the iron upon the ship's compass in the general case became necessary. Mr Airy devised the means of making this correction. By placing a magnet and a mass of iron in certain positions relative to the compass, the effect of the rest of the iron in the ship

is completely counteracted in all positions, [2]

But we have still to trace the progress of the theory

of terrestrial magnetism.

Theory of Terrestrial Magnetism. -Gilbert had begun plausible course of speculation on this point. 'We must reject, he says,13 'm the first place, that vulgar eminion of recent writers concerning magnetic mountains, or a certain magnetic rock, or an imaginary pole at a certain distance from the pole of the earth.' he adds, 'we learn by experience, that there is no such fixed pole or term in the earth for the variation.' Gilbert describes the whole earth as a magnetic globe, and attributes the variation to the irregular form of its protuberances, the solid parts only being magnetic. It was not easy to confirm or refute this opinion, but other hypotheses were tried by various writers; for instance, Halley had imagined, from the forms of the lines of equal variation, that there must be four magnetic poles; but Euler14 showed that the 'Halleian lines' would, for the most part, result from the suppoation of two magnetic poles, and assigned their posi-

¹² Sec Phil Trens, 1836,

tion so as to represent pretty well the known state of the variation all over the world in 1744. But the variation was not the only phenomenon which required to be taken into account; the dip at different places, and also the intensity of the force, were to be considered. We have already mentioned M. de Humboldt's collection of observations of the dip. These were examined by M. Biot, with the view of reducing them to the action of two poles in the supposed terrestrial magnetic axis. Having, at first, made the distance of these poles from the center of the earth indefinite, he found that his formulæ agreed more and more nearly with the observations, as the poles were brought nearer: and that fact and theory coincided tolerably well when both poles were at the center. In 1800,15 Krafft simplified this result, by showing that, on this supposition. the tangent of the dip was twice the tangent of the latitude of the place as measured from the magnetic equator. But M. Hansteen, who has devoted to the subject of terrestrial magnetism a great amount of labour and skill, has shown that, taking together all the observations which we possess, we are compelled to suppose four magnetic poles; two near the north pole, and two near the south pole, of the terrestrial globe: and that these poles, no two of which are exactly opposite each other, are all in motion, with different velocities, some moving to the east, and some to the west. This curious collection of facts awaits the hand of future theorists, when the ripeness of time shall invite them to the task.

[2nd Ed.] [I had thus written in the first edition. The theorist who was needed to reduce this accumulation of facts to their laws, had already laid his powerful hand upon them; namely, M. Gauss, a mathematician not inferior to any of the great men who completed the theory of gravitation. And institutions had been established for extending the collection of the facts pertaining to it, on a scale which elevates Magnetism into a companionship with Astronomy.

¹⁰ Enc. Met. p. 743.

M. Hansteen's Magnetismus der Erde was published in 1819. His conclusions respecting the position of the four magnetic 'poles' excited so much interest in his own country, that the Norwegian Storthing, or parliament, by a unanimous vote, provided funds for a magnetic expedition which he was to conduct along the north of Europe and Asia, and this they did at the very time when they refused to make a grant to the king for building a palace at Christiania. The expedition was made in 1828-30, and verified Hansteen's anticipations as to the existence of a region of magnetic convergence in Siberia, which he considered as indicating a 'pole' to the north of that country. M. Erman also travelled round the earth at the same time, making magnetic observations.

About the same time another magnetical phenomenon attracted attention. Besides the general motion of the magnetic poles, and the diurnal movements of the needle, it was found that small and irregular disturbances take place in its position, which M. de Humboldt termed magnetic storms. And that which excited a strong interest on this subject was the discovery that these magnetic storms, seen only by philosophers who watch the needle with microscopic exactness, rage simultaneously over large tracts of the surface of our globe. This was detected about 1825 by a comparison of the observations of M. Arago at Paris with simultaneous observations of M. Kupffer at Kasan in Russia.

distant more than 47 degrees of longitude.

At the instance of M. de Humboldt, the Imperial Academy of Russia adopted with zeal the prosecution of this inquiry, and formed a chain of magnetic stations across the whole of the Russian empire. Magnetic observations were established at Petersburg and at Kasan, and corresponding observations were made at Moscow, at Nicolaieff in the Crimea, and Barnaoul and Nertchinak in Siberia, at Sitka in Russian America, and even at Pekin. To these magnetic stations the Russian government afterwards added, Catharineburg in Russia Proper, Helsingfors in Finland, Teflis in Georgia. A comparison of the results

obtained at four of these stations made by MM. de Humboldt and Dove, in the year 1830, shewed that the magnetic disturbances were simultaneous, and

were for the most parallel in their progress.

Important steps in the prosecution of this subject were soon after made by M. Gauss, the great mathematician of Gottingen. He contrived instruments and modes of observation far more perfect than any before employed, and organized a system of comparative observations throughout Europe. In 1835, stations for this purpose were established at Altona, Augsburg, Berlin, Breda, Breslau, Copenhagen, Dublin, Freiberg, Gottingen, Greenwich, Hanover, Leipsic, Marburg, Milan, Munich, Petersburg, Stockholm, and Upsala. At these places, six times in the year, observations were taken simultaneously, at intervals of five minutes for 24 hours. The Results of the Magnetic Association (Resultaten des Magnetischen Vereins) were published

by MM. Gauss and Weber, beginning in 1836.

British physicists did not at first take any leading part in these plans. But in 1836, Baron Humboldt, who by his long labours and important discoveries in this subject might be considered as peculiarly entitled to urge its claims, addressed a letter to the Duke of Sussex, then President of the Royal Society, asking for the co-operation of this country in so large and hopeful a scheme for the promotion of science. The Royal Society willingly entertained this appeal; and the progress of the cause was still further promoted when it was zealously taken up by the British Association for the Advancement of Science, assembled at Newcastle in 1838. The Association there expressed its strong interest in the German system of magnetic observations; and at the instigation of this body, and of the Royal Society, four complete magnetical observatories were established by the British government, at Toronto, St. Helena, the Cape of Good Hope, and Van Diemen's Land. The munificence of the Directors of the East India Company founded and furnished an equal number at Simla (in the Himalayah), Madras, Bombay, and Sincapore. Sir Thomas Brisbane added

another at his own expense at Kelso, in Scotland. Besides this, the government sent out a naval expedition to make discoveries (magnetic among others,) in the Antarctic regions, under the command of Sir James Other states lent their assistance also, and founded or reorganized their magnetic observatories. Besides those already mentioned, one was established by the French government at Algiers; one by the Belgian, at Brussels, two by Austria, at Prague and Milan; one by Prussia, at Breslau, one by Bavaria, at Munich, one by Spain, at Cadiz; there are two in the United States, at Philadelphia and Cambridge, one at Cairo, founded by the Pasha of Egypt; and in India, one at Trevandrum, established by the Rajah of Travancore; and one by the King of Onde, at Lucknow. At all these distant stations the same plan was followed out, by observations strictly simultaneous, made according to the same methods, with the same instrumental means. Such a scheme, combining world-wide extent with the singleness of action of an individual mind, is hitherto without parallel

At first, the British stations were established for three years only, but it was thought advisable to extend this period three years longer, to end in 1845. And when the termination of that period arrived, a discussion was held among the magneticians themselves, whether it was better to continue the observations still, or to examine and compare the vast mass of observations already collected, so as to see to what results and improvements of methods they pointed. This question was argued at the meeting of the British Association at Cambridge in that year; and the conference ended in the magneticians requesting to have the observations continued, at some of the observatories for an indefinite period, at others, till the year 1848. In the mean time the Antarctic expedition had brought back rich store of observations, fitted to disclose the magnetic condition of those regions which it had These were discussed, and their results exhibited, in the Philosophical Transactions for 1843, by Col. Sabine, who had himself, at various periods, made magnetic observations in the Arctic regions, and in several remote parts of the globe, and had always been a zealous labourer in this fruitful field. The general mass of the observations was placed under the management of Professor Lloyd, of Dublin, who has enriched the science of magnetism with several valuable instruments and methods, and who, along with Col. Sabine, made a magnetic survey of the British Isles in 1835 and 1836.

I do not dwell upon magnetic surveys of various countries made by many excellent observers; as MM.

Quetelet, Forbes, Fox, Bache and others.

The facts observed at each station were, the intensity of the magnetic force; the declination of the needle from the mendian, sometimes called the variation; and its inclination to the horizon, or the dip :- or at least, some elements equivalent to these. The values of these elements at any given time, if known, can be expressed by charts of the earth's surface, on which are drawn the isodynamic, isogonal, and isoclinal curves. The second of these kinds of charts contain the 'Halleian lines' spoken of in a previous page. Moreover the magnetic elements at each place are to be observed in such a manner as to determine both their periodical variations, (the changes which occur in the period of a day, and of a year,) the secular changes, as the gradual increase or diminution of the declination at the same place for many years; and the irregular fluctuations which, as we have said, are simultaneous over a large part, or the whole, of the earth's surface.

When these Facts have been ascertained over the whole extent of the earth's surface, we shall still have to inquire what is the Cause of the changes in the forces which these phenomena disclose. But as a basis for all speculation on that subject, we must know the law of the phenomena, and of the forces which immediately produce them—I have already said that Euler tried to account for the Halleian lines by means of two magnetic 'poles,' but that M. Hansteen conceived it necessary to assume four. But an entirely new light has been thrown upon this subject by the beautiful

investigations of Gauss, in his Theory of Terrestrial Magnetism published in 1839 He remarks that the term 'poles,' as used by his predecessors, involves an assumption arbitrary, and, as it is now found, false; namely, that certain definite points, two, four, or more, scung according to the laws of ordinary magnetical poles, will explain the phenomena. He starts from a more comprehensive assumption, that magnetism is distributed throughout the mass of the earth in an unknown manner On this assumption he obtains a function V, by the differentials of which the elements of the magnetic force at any point will be expressed. This function V is well known in physical astronomy, and is obtained by summing all the elements of magnetic force in each particle, each multiplied by the reciprocal of its distance, or as we may express it, by taking the sum of each element and its proximity jointly. Hence it has been proposed 16 to term this function the 'integral proximity' of the attracting mass. 17 By using the most refined mathematical artifices for deducing the values of V and its differentials in converging series, he is able to derive the coefficients of these series from the observed magnetic elements at certain places, and hence, to calculate them for all places. The comparison of the calculation with the observed results is, of course, the test of the truth of the theory.

The degree of convergence of the series depends

stant occurrence in investiga. On the other hand, the term /ntions respecting attractions. It tegral Proximity does not indicate is introduced by Laplace in his that which gives the function investigations respecting the at- its peculiar claim to distinction; tractions of apheroids, Méc. upon the unknown distribution of magnetism within the earth. 'If we could venture to assume,' says M. Gauss, 'that the members have a sensible influence only as far as the fourth order, complete observations from eight points would be sufficient, theoretically considered, for the determination of the coefficients. And under certain limitations, making this assump tion, as the best we can do at present, M. Gamobtains from eight places, 24 coefficients (each place supplying three elements), and hence calculates the magnetic elements (intensity, variation and dip) at or places in all parts of the earth. He finds his calculations approach the observed values with a degree of exactness which appears to be quite convincing as to the general truth of his results; especially taking into account how entirely unlimited is his original

hypothesis.

It is one of the most curious results of this investigation that according to the most simple meaning which we can give to the term 'pole,' the earth has only two magnetic poles; that is, two points where the direction of the magnetic force is vertical. And thus the isogonal curves may be looked upon as deformations of the curves deduced by Euler from the supposition of two poles, the deformation arising from this, that the earth does not contain a single definite magnet but irregularly diffused magnetical elements, which still have collectively a distant resemblance to a single magnet. And instead of Hansteen's Siberian pole. we have a Siberian region in which the needles converge; but if the apparent convergence be pursued it nowhere comes to a point; and the like is the case in the Antarctic region. When the 24 Gaussian elements at any time are known the magnetic condition of the globe is known, just as the mechanical condition of the solar system is known, when we know the elements of the orbits of the satellites and planets and the man of each. And the comparison of this magnetic condition of the globe at distant periods of time cannot fail to supply materials for future researches and speculations with regard to the agencies by which the condition of the earth is determined. The condition of which we here speak must necessarily be its mechanico-chemical condition, being expressed, as it will be, in terms of the mechanico-chemical sciences. The investigations I have been describing belong to the mechanical side of the subject; but when philosophers have to consider the causes of the secular changes which are found to occur in this mechanical condition, they cannot fail to be driven to electrical, that is, chemical agencies and laws.

I can only allude to Gauss's investigations respecting the Absolute Measure of the Earth's Magnetic Force. To determine the ratio of the magnetic force of the earth to that of a known magnet, Poisson proposed to observe the time of vibration of a second magnet. The method of Gauss, now universally adopted, consists in observing the position of equilibrium of the second

magnet when deflected by the first.

The manner in which the business of magnetic observation has been taken up by the governments of our time makes this by far the greatest scientific undertaking which the world has ever seen. The result will be that we shall obtain in a few years a knowledge of the magnetic constitution of the earth which otherwise it might have required centuries to accumulate. The secular magnetic changes must still require a long time to reduce to their laws of phenomena, except observation be anticipated or assisted by some happy discovery as to the causes of these changes. But besides the special gain to magnetic science by this great plan of joint action among the nations of the earth, there is thereby a beginning made in the recognition and execution of the duty of forwarding science in general by national exertions. For at most of the magnetic observations, meteorological observations are also carried on; and such observations, being far more extensive, systematic, and permanent than those which have usually been made, can hardly fail to produce important additions to science. But at any rate they do for science that which nations can do, and individuals cannot; and they seek for scientific truths in a manner suitable to the respect now professed for science and to the progress which its methods have made. Nor are we to overlook the effect of such observations as means of training men in the pursuit of science. 'There is amongst us, says one of the magnetic observers, 'a growing recognition of the importance, both for science and for practical life, of forming exact observers of nature. Hitherto astronomy alone has afforded a very partial opportunity for the formation of fine observers, of which few could avail themselves. Experience has shown that magnetic observations may serve

as excellent training schools in this respect. 18]

The various other circumstances which terrestrial magnetism exhibits,—the diurnal and annual changes of the position of the compass-needle;—the larger secular change which affects it in the course of years;the difference of intensity at different places, and other facts, have naturally occupied philosophers with the attempt to determine, both the laws of the phenomena and their causes. But these attempts necessarily depend, not upon laws of statical magnetism, such as they have been explained above; but upon the laws by which the production and intensity of magnetism in different cases are regulated, -laws which belong to a different province, and are related to a different set of principles. Thus, for example, we have not attempted to explain the discovery of the laws by which heat influences ungnetism; and therefore we cannot now give an account of those theories of the facts relating to terrestrial magnetism, which depend upon the influence of temperature. The conditions of excitation of magnetism are best studied by comparing this force with other cases where the same effects are produced by very different apparent agencies; such as galvanio and thermo-electricity. To the history of these we shall presently proceed.

Conclusion. The hypothesis of magnetic fluids, as physical realities, was never widely or strongly em-

¹⁸ Letter of W. Weber, Brit. Asioc. Rep. 1845. p. 17.

braced, as that of electric fluids was. For though the hypothesis accounted, to a remarkable degree of exactness, for large classes of the phenomena, the presence of a material fluid was not indicated by facts of a different kind, such as the spark, the discharge from points, the shock, and its mechanical effects. Thus the belief of a peculiar magnetic fluid or fluids was not forced upon men's minds; and the doctrine above stated was probably entertained by most of its adherents, chiefly as a means of expressing the laws of

phenomena in their elementary form.

One other observation occurs here. We have seen that the supposition of a fluid moveable from one part of bodies to another, and capable of accumulation in different parts of the surface, appeared at first to be as distinctly authorized by magnetic as by electric phenomena; and yet that it afterwards appeared, by calculation, that this must be considered as a derivative result, no real transfer of fluid taking place except within the limits of the insensible particles of the body Without attempting to found a formula of philosophizing on this circumstance, we may observe, that this occurrence, like the disproof of heat as a material fluid, shows the possibility of an hypothesis which shall very exactly satisfy many phenomena, and yet be incomplete: it shows, too, the necessity of bringing facts of all kinds to bear on the hypothesis; thus, in this case it was requisite to take into account the facts of junction and separation of magnetic bodies, as well as their attractions and repulsions.

If we have seen reason to doubt the doctrine of electric fluids as physical realities, we cannot help pronouncing upon the magnetic fluids as having still more insecure claims to a material existence, even on the grounds just stated. But we may add considerations still more decisive; for at a further stage of discovery, as we shall see, magnetic and electric action were found to be connected in the closest manner, so as to lead to the persuasion of their being different effects of one common cause. After those discoveries,

no philosopher would dream of assuming electric fluids and magnetic fluids as two distinct material agents. Yet even now the nature of the dependence of magnetism upon any other cause is extremely difficult to conceive. But till we have noticed some of the discoveries to which we have alluded, we cannot even speculate about that dependence. We now, therefore, proceed to sketch the history of these discoveries.

MECHANICO-CHEMICAL SCIENCES.

(CONTINUED.)

HISTORY OF GALVANISM,

OR

VOLTAIC ELECTRICITY.

Percusse gelido trepidant sub pectore fibre,
Et nova desuetis subrepens vita medullis
Miscetur morti: tunc omnis palpitat artus
Tenduntur nervi; nec se tellure cadaver
Paullatim per membra levat; terraque repulsum est
Erectumque simul.

LUCAN. vi. 752.

The form which lay before inert and dead,
Sudden a piercing thrill of change o'erspread;
Returning life gleams in the stony face,
The fibres quiver and the sinews brace,
Move the stiff limbs;—nor did the body rise
With tempered strength which genial life supplies,
But upright starting, its full stature held,
As though the earth the supine corse repelled.

CHAPTER I.

DISCOVERY OF VOLTAIC ELECTRICITY.

TE have given the name of mechanico-chemical to the class of sciences now under our consideration; for these sciences are concerned with cases in which mechanical effects, that is, attractions and repulsions, are produced, while the conditions under which these effects occur, depend, as we shall hereafter see, on chemical relations. In that branch of these sciences which we have just treated of, Magnetism, the mechanical phenomena were obvious, but their connexion with chemical causes was by no means apparent, and, indeed,

has not yet come under our notice.

The subject to which we now proceed, Galvanism, belongs to the same group, but, at first sight, exhibits only the other, the chemical, portion of the features of the class; for the connexion of galvanic phenomena with chemical action was soon made out, but the mechanical effects which accompany them were not examined till the examination was required by a new train of discovery. It is to be observed, that I do not include in the class of mechanical effects the convulsive motions in the limbs of animals which are occasioned by galvanic action; for these movements are produced, not by attraction and repulsion, but by muscular irritability; and though they indicate the existence of a peculiar agency, cannot be used to measure its intensity and law.

The various examples of the class of agents which we here consider,—magnetism, electricity, galvanism, electro-magnetism, thermo-electricity,—differ from each other principally in the circumstances by which they are called into action; and these differences are in reality of a chemical nature, and will have to be considered when we come to treat of the inductive steps by which the general principles of chemical theory are established. In the present part of our task,

therefore, we must take for granted the chemical conditions on which the excitation of these various kinds of action depends, and trace the history of the discovery of their mechanical laws only. This rule will much abridge the account we have here to give of the progress of discovery in the provinces to which I have

just referred.

The first step in this career of discovery was that made by Galvani, Professor of Auatomy at Bologna. In 1790, electricity, as an experimental science, was nearly stationary. The impulse given to its progress by the splendid phenomena of the Leyden phial had almost died away; Coulomb was employed in systematizing the theory of the electric fluid, as shown by its statical effects; but in all the other parts of the subject, no great principle or new result had for some time been detected. The first announcement of Galvani's discovery in 1791 excited great notice, for it was given forth as a manifestation of electricity under a new and remarkable character; namely, as residing in the muscles of animals.1 The limbs of a dissected frog were observed to move, when touched with pieces of two different metals; the agent which produced these motions was conceived to be identified with electricity, and was termed animal electricity, and Galvani's experiments were repeated, with various modifications, in all parts of Europe, exciting much curiosity, and giving rise to many speculations.

It is our business to determine the character of each great discovery which appears in the progress of science. Men are fond of repeating that such discoveries are most commonly the result of accident; and we have seen reason to reject this opinion, since that preparation of thought by which the accident produces discovery is the most important of the conditions on which the successful event depends. Such accidents are like a spark which discharges a gun already loaded and pointed. In the case of Galvant, indeed, the discovery may, with more propriety than usual, be said

¹ De Viribus Electricis in Mota Muscular . Comm Benon. t. vil. 1794.

to have been casual; but, in the form in which it was first noted, it exhibited no important novelty. His frog was lying on a table near the conductor of an electrical machine, and the convulsions appeared only when a spark was taken from the machine. If Galvani had been as good a physicist as he was an anatomist, he would probably have seen that the movements so occasioned, proved only that the muscles or nerves, or the two together, formed a very sensitive indicator of electrical action. It was when he produced such motions by contact of metals alone, that he obtained an

important and fundamental fact in science.

The analysis of this fact into its real and essential conditions was the work of Alexander Volta, another Italian professor. Volta, indeed, possessed that knowledge of the subject of electricity which made a hint like that of Galvani the basis of a new science. Galvani appears never to have acquired much general knowledge of electricity: Volta, on the other hand, had laboured at this branch of knowledge from the age of eighteen, through a period of nearly thirty years; and had invented an electrophorus and an electrical condenser, which showed great experimental skill. When he turned his attention to the experiments made by Galvani, he observed that the author of them had been far more surprized than he needed to be, at those results in which an electrical spark was produced; and that it was only in the cases in which no such apparatus was employed, that the observations could justly be considered as indicating a new law, or a new kind of electricity. He soon satisfied himself's (about 1794) that the essential conditions of this kind of action depended on the metals;—that it is brought into play most decidedly when two different metals touch each other, and are connected by any moist body; -and that the parts of animals which had been used discharged the office both of such moist bodies, and of very sensitive electrometers. The animal electricity

^{*} Phil. Trans 1793, p. 21.

³ See Flacher, vin 625.

of Galvani might, he observed, be with more propriety called metallic electricity.

The recognition of this agency as a peculiar kind of electricity, arose in part perhaps, at first, from the confusion made by Galvani between the cases in which his electrical machine was, and those in which it was not, employed. But the identity was confirmed by its being found that the known difference of electrical conductors and non-conductors regulated the conduction of the new influence. The more exact determination of the new facts to those of electricity was a succeeding step of the progress of the subject.

The term 'animal electricity' has been superseded by others, of which galvanism is perhaps the most familiar. I think it will appear from what has been said, that Volta's office in this discovery is of a much higher and more philosophical kind than that of Galvani; and it would, on this account, be more fitting to employ the term voltaic electricity; which, indeed, is very commonly used, especially by our most recent and

comprehensive writers.

Volta more fully still established his claim as the main originator of this science by his next step. When some of those who repeated the experiments of Galvani had expressed a wish that there was some method of multiplying the effect of this electricity, such as the Leyden phial supplies for common electricity, they probably thought their wishes far from a realization. But the voltaic pile, which Volta described in the Philosophical Transactions for 1800, completely satisfies this aspiration; and was, in fact, a more important step in the history of electricity than the Leyden jar had been. It has since undergone various modifications, of which the most important was that introduced by Crunkshanks, who substituted a trough for a pile. But in all cases the principle of the instrument was the same;—a continued repetition of the triple combination of two metals and a fluid in contact, so as to form a circuit which returns into itself.

^{*} Fischer, viii. p. 683.

DISCOVERY OF VOLTAIC ELECTRICITY.

Such an instrument is capable of causing effects of great intensity, as seen both in the production of light and heat, and in chemical changes. But the discovery with which we are here concerned, is not the details and consequences of the effects, (which belong to chemistry,) but the analysis of the conditions under which such effects take place; and this we may consider as completed by Volta at the epoch of which we speak.

CHAPTER IL

RECEPTION AND CONFIRMATION OF THE DISCOVERY OF VOLTAIC ELECTRICITY.

GALVANI'S experiments excited a great interest of all over Europe, in consequence partly of a circumstance which, as we have seen, was unessential, the muscular contractions and various sensations which they occasioned. Galvani himself had not only considered the animal element of the circuit as the origin of the electricity, but had framed a theory, in which he compared the muscles to charged jars, and the nerves to the discharging wires; and a controversy was, for some time, carried on, in Italy, between the adherents of Galvani and those of Volta.²

The galvanic experiments, and especially those which appeared to have a physiological bearing, were verified and extended by a number of the most active philosophers of Europe, and especially William von Humboldt. A commission of the Institute of France, appointed in 1797, repeated many of the known experiments, but does not seem to have decided any disputed points. The researches of this commission referred rather to the discoveries of Galvani than to those of Volta. The latter were, indeed, hardly known in France till the conquest of Italy by Bonaparte, in 1801. France was, at the period of these discoveries, separated from all other countries by war, and especially from England, where Volta's Memoirs were published.

The political revolutions of Italy affected, in very different manners, the two discoverers of whom we speak. Galvani refused to take an oath of allegiance to the Cisalpine republic, which the French conqueror established; he was consequently stripped of all his

¹ Fischer, vili. 613. ² Ib vili. 619. ³ Blog Unio, art. Folia, (by Biot.)

offices; and, deprived, by the calamities of the times, of most of his relations, he sank into poverty, melancholy, and debility. At last his scientific reputation induced the republican rulers to decree his restoration to his professorial chair; but his claims were recognized too late, and he died without profiting by this

intended favour, in 1798.

Volta, on the other hand, was called to Paris by Bonaparte as a man of science, and invested with honours, emoluments, and titles. The conqueror himself, indeed, was strongly interested by this train of research. He himself founded valuable prizes, expressly with a view to promote its prosecution. At this period, there was something in this subject pecuharly attractive to his Italian mind; for the first glumpses of discoveries of great promise have always excited an enthusiastic activity of speculation in the philosophers of Italy, though generally accompanied with a want of precise thought. It is narrated 5 of Bonaparte, that after seeing the decomposition of the salts by means of the voltaic pile, he turned to Corvisart, his physician, and said, 'Here, doctor, is the image of life; the vertebral column is the pile, the liver is the negative, the bladder the positive, pole.' The importance of voltage researches is not less than it was estimated by Bonaparte; but the results to which it was to lead were of a kind altogether different from those which thus suggested themselves to his mind. The connexion of mechanical and chemical action was the first great point to be dealt with; and for this purpose the laws of the mechanical action of voltaic electricity were to be studied.

It will readily be supposed that the voltaic researches, thus begun, opened a number of interesting topics of examination and discussion. These, however, it does not belong to our place to dwell upon at present; since they formed parts of the theory of the subject, which was not completed till light had been thrown upon it from other quarters. The identity of

Becquerel, Traité d'Electr. t. l. p. 107.

⁵ lb t.l.p. 108.

galvanism with electricity, for instance, was at first, as we have intimated, rather conjectured than proved. It was denied by Dr. Fowler, in 1793; was supposed to be confirmed by Dr. Wells two years later, but was, still later, questioned by Davy. The nature of the operation of the pile was variously conceived. Volta himself had obtained a view of it which succeeding researches confirmed, when he asserted in 1800, that it resembled an electric battery feebly charged and constantly renewing its charge. In pursuance of this view, the common electrical action was, at a later period (for instance by Ampère, in 1820), called electrical tension, while the voltaic action was called the electrical current, or electromotive action. The different effects produced, by increasing the size and the number of the plates in the voltaic trough, were also very remarkable. The power of producing heat was found to depend on the size of the plates, the power of producing chemical changes, on the other hand, was augmented by the number of plates of which the battery consisted. The former effect was referred to the increased quantity, the latter to the intensity, of the electric fluid. We mention these distinctions at present, rather for the purpose of explaining the language in which the results of the succeeding investigations are narrated, than with the intention of representing the hypotheses and measures which they imply, as clearly established, at the period of which we speak. For that purpose new discoveries were requisite, which we have soon to relate.

⁶ Phil. Trans p. 403.

CHAPTER III.

DISCOVERY OF THE LAWS OF THE MUTUAL ATTRAC-TION AND REPULSION OF VOLTAIC CURRENTS.— AMPÈRE.

N order to show the place of voltaic electricity I among the mechanico-chemical sciences, we must speak of its mechanical laws as separate from the laws of electro-magnetic action, although, in fact, it was only in consequence of the forces which conducting voltaic wires exert upon magnets, that those forces were detected which they exert upon each other. This latter discovery was made by M. Ampère; and the extraordinary rapidity and sagacity with which he caught the suggestion of such forces, from the electromagnetic experiments of M. Oersted, (of which we shall speak in the next chapter,) well entitle him to be considered as a great and independent discoverer. As he truly says, 'it by no means followed, that because a conducting wire exerted a force on a magnet, two conducting wires must exert a force on each other; for two pieces of soft iron, both of which affect a magnet, do not affect each other.' But immediately on the promulgation of Oersted's experiments, in 1820, Ampere leapt forwards to a general theory of the facts, of which theory the mutual attraction and repulsion of conducting voltaic wires was a fundamental supposition. The supposition was immediately verified by direct trial; and the laws of this attraction and repulsion were soon determined, with great experimental ingenuity, and a very remarkable command of the resources of analysis. But the experimental and anslytical investigation of the mutual action of voltaic or electrical currents, was so mixed up with the examination of the laws of electro magnetism, which had given occasion to the investigation, that we must not

¹ Theorie des Phénom. Electrodynamiques, p. 113.

treat the two provinces of research as separate. The mention in this place, premature as it might appear, of the labours of Ampère, arises inevitably from his being the author of a beautiful and comprehensive generalization, which not only included the phenomena exhibited by the new combinations of Oersted, but also disclosed forces which existed in arrangements already familiar, although they had never been detected till the theory pointed out how they were to be looked for.

CHAPTER IV.

DISCOVERY OF ELECTRO-MAGNETIC ACTION.—
ORBSTED.

THE impulse which the discovery of galvanism, in 1791, and of the voltage pile, in 1800, had given to the study of electricity as a mechanical science, had nearly died away in 1820. It was in that year that M. Oersted, of Copenhagen, announced that the conducting wire of a voltage circuit acts upon a magnetic needle, and thus recalled into activity that endeavour to connect magnetism with electricity, which, though apparently on many accounts so hopeful, had hitherto been attended with no success. Oersted found that the needle has a tendency to place itself at right angles to the wire;—a kind of action altogether different from

any which had been suspected.

This observation was of vast importance; and the analysis of its conditions and consequences employed the best philosophers in Europe immediately on its promulgation. It is impossible, without great injustice, to refuse great ment to Oersted as the author of the discovery. We have already said, that men appear generally inclined to believe remarkable discoveries to be accidental, and the discovery of Oersted has been spoken of as a casual insulated experiment.1 Oersted had been looking for such an accident probably more carefully and perseveringly than any other person in Europe. In 1807, he had published a work, in which he professed that his purpose was 'to ascertain whether electricity, in its most latent state, had any effect on the magnet' And he, as I know from his own declaration, considered his discovery as the natural sequel and confirmation of his carly researches; as, indeed, it fell in readily and immediately

See Schelling ucher Faraday's Entdeckung, p. 27.
2 Ampere, p. 63.

with speculations on these subjects then very prevalent in Germany. It was an accident like that by which a man guesses a riddle on which his mind has long been

employed.

Besides the confirmation of Oersted's observations by many experimenters, great additions were made to his facts; of these, one of the most important was due to Ampère. Since the earth is in fact magnetic, the voltaic wire ought to be affected by terrestrial magnetism alone, and ought to tend to assume a position depending on the position of the compass needle. At first, the attempts to produce this effect failed, but soon, with a more delicate apparatus, the result was found to agree with the auticipation.

It is impossible here to dwell on any of the subsequent researches, except so far as they are essential to our great object, the progress towards a general theory of the subject. I proceed, therefore, immediately to

the attempts made towards this object.

CHAPTER V.

DISCOVERY OF THE LAWS OF ELECTRO-MAGNETIC ACTION.

N attempting to analyse the electro-magnetic phenomena observed by Oersted and others into their simplest forms, they appeared, at least at first sight, to be different from any mechanical actions which had yet been observed. It seemed as if the conducting wire exerted on the pole of the magnet a force which was not attractive or repulsive, but transverse; not tending to draw the point acted on nearer, or to push it further off, in the line which reached from the acting point, but urging it to move at right angles to this line. The forces appeared to be such as Kepler had dreamt of in the infancy of mechanical conceptions; rather than such as those of which Newton had established the existence in the solar system, and such as he, and all his successors, had supposed to be the only kinds of force which exist in nature. The north pole of the needle moved as if it were impelled by a vortex revolving round the wire in one direction, while the south pole seemed to be driven by an The case seemed novel, and almost upposite vortex. paradoxical.

It was soon established by experiments, made in a great variety of forms, that the mechanical action was really of this transverse kind. And a curious result was obtained, which a little while before would have been considered as altogether incredible;—that this force would cause a constant and rapid revolution of either of the bodies about the other;—of the conducting wire about the magnet, or of the magnet about the conducting wire. This was effected by Mr. Faraday,

in 1821.

The laws which regulated the intensity of this force, with reference to the distance and position of the bodies, now naturally came to be examined. MM. Biot

and Savart in France, and Mr. Barlow in England, instituted such measures; and satisfied themselves that the elementary force followed the law of magnitude of all known elementary forces, in being inversely as the square of the distance; although, in its direction, it was so entirely different from other forces. But the investigation of the laws of phenomena of the subject was too closely connected with the choice of a mechanical theory, to be established previously and independently, as had been done in astronomy. The experiments gave complex results, and the analysis of these into their elementary actions was almost an indispensable step in order to disentangle their laws. We must, therefore, state the progress of this analysis.

CHAPTER VI.

THEORY OF ELECTRODYNAMICAL ACTION.

AMPÈRE'S Theory —Nothing can show in a more striking manner the advanced condition of physical speculation in 1820, than the reduction of the strange and complex phenomena of electromagnetism to a simple and general theory as soon as they were published. Instead of a gradual establishment of laws of phenomena, and of theories more and more perfect, occupying ages, as in the case of astronomy, or generations, as in the instances of magnetism and electricity, a few months sufficed for the whole process of generalization; and the experiments made at Copenhagen were announced at Paris and London, almost at the same time with the skilful analysis and comprehensive inductions of Ampère.

Yet we should err if we should suppose, from the celerity with which the task was executed, that it was an easy one. There were required, in the author of such a theory, not only those clear conceptions of the relations of space and force, which are the first conditions of all sound theory, and a full possession of the experiments, but also a masterly command of the mathematical arms by which alone the victory could be gained, and a sagacious selection of proper experiments which might decide the fate of the proposed

hypothesis,

It is true, that the nature of the requisite hypothesis was not difficult to see in a certain vague and limited way. The conducting-wire and the magnetic needle had a tendency to arrange themselves at right angles to one another. This might be represented by supposing the wire to be made up of transverse magnetic needles, or by supposing the needle to be made up of transverse conducting-wires; for it was easy to conceive forces which should bring corresponding elements, either magnetic or voltaic, into parallel positions; and

then the general phenomena above stated would be accounted for. And the choice between the two modes of conception, appeared at first sight a matter of indifference. The majority of philosophers at first adopted, or at least employed, the former method, as Oersted in Germany, Berzelius in Sweden, Wollaston

in England.

Ampère adopted the other view, according to which the magnet is made up of conducting-wires in a transverse position. But he did for his hypothesis what no one did or could do for the other: he showed that it was the only one which would account, without additional and arbitrary suppositions, for the facts of continued motion in electro-magnetic cases. And he further elevated his theory to a higher rank of generality, by showing that it explained, not only the action of a conducting-wire upon a magnet, but also two other classes of facts, already spoken of in this history,—the action of magnets upon each other, and the action of conducting-wires upon each other.

The deduction of such particular cases from the theory, required, as may easily be imagined, some complex calculations but the deduction being satisfactory, it will be seen that Ampère's theory conformed to that description which we have repeatedly had to point out as the usual character of a true and stable theory; namely, that besides accounting for the class of phenomena which suggested it, it supplies an unforeseen explanation of other known facts. For the mutual action of magnets, which was supposed to be already reduced to a satisfactory theoretical form by Coulomb, was not contemplated by Ampère in the formation of his hypothesis, and the mutual action of voltaic currents, though tried only in consequence of the suggestion of the theory, was clearly a fact distinct from electromagnetic action, yet all these facts flowed alike from the theory. And thus Ampère brought into view a class of forces for which the term 'electromagnetic' was too limited, and which he designated by the

¹ Ann. de Chim., tom. xx. p. 60 (1842).

appropriate term electrodynamic; distinguishing them by this expression, as the forces of an electric current, from the electrical effects of electricity which we had formerly to treat of. This term has passed into common use among scientific writers, and remains the record and stamp of the success of the Amperian induction.

The first promulgation of Ampère's views was by a communication to the French Academy of Sciences, September the 18th, 1820, Oersted's discoveries having reached Paris only in the preceding July. At almost every meeting of the Academy during the remainder of that year and the beginning of the following one, he had new developments or new confirmations of his theory to announce. The most hypothetical part of his theory,—the proposition that magnets might be considered in their effects as identical with spiral voltaic wires, he asserted from the very first. The mutual attraction and repulsion of voltaic wires, -the laws of this action,—the deduction of the observed facts from it by calculation,—the determination, by new experiments, of the constant quantities which entered into his formulæ, -followed in rapid succession. The theory must be briefly stated. It had already been seen that parallel voltage currents attracted each other; when, instead of being parallel, they were situate in any directions, they still exerted attractive and repulsive forces depending on the distance, and on the directions of each element of both currents. Add to this doctrine the hypothetical constitution of magnets, namely, that a voltage current runs round the axis of each particle, and we have the means of calculating a vast variety of results which may be compared with experiment. But the laws of the elementary forces required further fixation. What functions are the forces of the distance and the directions of the elements?

To extract from experiment an answer to this inquiry was far from easy, for the elementary forces were mathematically connected with the observed facts, by a double mathematical integration;—a long, and, while the constant coefficients remained undefined, hardly a possible operation. Ampère made some trials in this

way, but his happier genius suggested to him a better path. It occurred to him, that if his integrals, without being specially found, could be shown to vanish upon the whole, under certain conditions of the problem, this circumstance would correspond to arrangements of his apparatus in which a state of equilibrium was preserved, however the form of some of the parts night be changed. He found two such cases, which were of great importance to the theory. The first of these cases proved that the force exerted by any element of the voltage wire might be resolved into other forces by a theorem resembling the well-known proposition of the parallelogram of forces. This was proved by showing that the action of a straight wire is the same with that of another wire which joins the same extremities, but is bent and contorted in any way whatever. But it still remained necessary to determine two fundamental quantities; one of which expressed the power of the distance according to which the force varied; the other, the degree in which the force is affected by the obliquity of the elements. One of the general causes of equilibrium, of which we have spoken, gave a relation between these two quantities: 3 and as the power was naturally, and, as it afterwards appeared. rightly, conjectured to be the inverse square, the other quantity also was determined; and the general problem of electrodynamical action was fully solved.

If Ampère had not been an accomplished analyst, he would not have been able to discover the condition on which the nullity of the integral in this case depended. And throughout his labours, we find reason to admire, both his mathematical skill, and his steadiness of thought; although these excellencies are by no means accompanied throughout with corresponding clearness

and elegance of exposition in his writings.

Reception of Ampère's Theory.—Clear mathematical conceptions, and some familiarity with mathematical operations, were needed by readers also, in order to

² Communication to the Acad. Sc., June 10, 1822. See Ampère, Recueil, p. 292.

² Recueil, p. 314.

appreciate the evidence of the theory; and, therefore, we need not feel any surprise if it was, on its publication and establishment, hailed with far less enthusiasm than so remarkable a triumph of generalizing power might appear to deserve. For some time, indeed, the greater portion of the public were naturally held in suspense by the opposing weight of rival names. The Amperian theory did not make its way without contention and competition. The electro magnetic experimenta, from their first appearance, gave a clear promise of some new and wide generalization; and held out a prize of honour and fame to him who should be first in giving the right interpretation of the riddle. In France, the emulation for such reputation is perhaps more vigilant and anxious than it is elsewhere; and we see, on this as on other occasions, the scientific host of Paris springing upon a new subject with an impetuosity which, in a short time, runs into controversies for priority or for victory. In this case, M. Biot, as well as Ampère, endeavoured to reduce the electromagnetic phenomena to general laws. The discussion between him and Ampère turned on some points which are currous. M Biot was disposed to consider as an elementary action, the force which an element of a voltaic wire exerts upon a magnetic particle, and which is, as we have seen, at right angles to their mutual distance; and he conceived that the equal reaction which necessarily accompanies this action acts oppositely to the action, not in the same line, but in a parallel line, at the other extremity of the distance; thus forming a primitive couple, to use a technical expression borrowed from mechanics. To this Ampère objected,4 that the direct opposition of all elementary ection and reaction was a universal and necessary mechanical law. He showed too that such a couple as had been assumed, would follow as a derivative result from his theory. And in comparing his own theory with that in which the voltaic wire is assimilated to a collection of transverse nugnets, he was also able to

^{*} Ampère, Théorie, p. 154.

prove that no such assemblage of forces acting to and from fixed points, as the forces of magnets do act, could produce a continued motion like that discovered by Faraday. This, indeed, was only the well-known demonstration of the impossibility of a perpetual motion. If, instead of a collection of magnets, the adverse theorists had spoken of a magnetic current, they might probably interpret their expressions so as to explain the facts; that is, if they considered every element of such a current as a magnet, and consequently, every point of it as being a north and a south pole at the same instant. But to introduce such a conception of a magnetic current was to abandon all the laws of magnetic action hitherto established; and consequently to lose all that gave the hypothesis its value. The idea of an electric current, on the other hand, was so far from being a new and hazardous assumption, that it had already been forced upon philosophers from the time of Volta; and in this current, the relation of preceding and succeeding, which necessarily existed between the extremities of any element. introduced that relative polarity on which the success of the explanations of the facts depended. And thus in this controversy, the theory of Ampère has a great and undeniable superiority over the rival hypotheses.

CHAPTER VII.

COSSEQUENCES OF THE ELECTRODYNAMIC THEORY,

which were soon made of the electro-magnetic discoveries. But we may notice one of the most important,—the Galvanometer, an instrument which, by enabling the philosopher to detect and to measure extremely minute electrodynamic actions, gave an impulse to the subject similar to that which it received from the invention of the Leyden Phial, or the Voltaic Pile. The strength of the voltaic current was measured, in this instrument, by the deflection produced in a compass-needle; and its sensibility was multiplied by making the wire pass repeatedly above and below the needle. Schweigger, of Halle, was one of the first devisers of this apparatus.

The substitution of electro-magnets, that is, of spiral tubes composed of voltaic wires, for common magnets, gave rise to a variety of curious apparatus and speculations, some of which I shall hereafter mention.

[2nd Ed.] [When a voltaic apparatus is in action, there may be conceived to be a current of electricity running through its various elements, as stated in the text. The force of this current in various parts of the circuit has been made the subject of mathematical investigation by M. Ohm. The problem is in every respect similar to that of the flow of heat through a body, and taken generally, leads to complex calculations of the same kind. But Dr. Ohm, by limiting the problem in the first place by conditions which the usual nature and form of voltaic apparatus suggest, has been able to give great simplicity to his reasonings. These conditions are, the linear form of the conductors (wires) and the steadiness of the electric state. For this part of the problem Dr. Ohm's reasonings are as

¹ Die Galvanische Kette Mathematisch bearbeitet von Dr. G S. Ohm. Berlin, 1827.

simple and as demonstrative as the elementary propositions of Mechanics. The formulæ for the electric force of a voltaic current to which he is led have been experimentally verified by others, especially Fechner,³ Gauss,3 Lenz, Jacobi, Poggendorf, and Pouillet.

Among ourselves, Mr. Wheatstone has confirmed and applied the views of M. Ohm, in a Memoir On New Instruments and Processes for determining the Constants of a Voltaic Circuit. He there remarks, that the clear ideas of electromotive forces and resistances, substituted by Ohm for the vague notions of quantity and intensity which have long been prevalent, give satisfactory explanations of the most important difficulties, and express the laws of a vast number of phenomena in formulæ of remarkable simplicity and generality. In this Memoir, Professor Wheatstone describes an instrument which he terms the Rheastat, because it brings to a common standard the voltaic currents which are compared by it. He generalizes the language of the subject by employing the term rheomotor for any apparatus which originates an electric current (whether voltage or thermoelectric, &c.) and rheometer for any instrument to measure the force of such a current. It appears that the idea of constructing an instrument of the nature of the Rheostat had occurred also to Prof. Jacobi, of St. Petersburg.

The galvanometer led to the discovery of another class of cases in which the electrodynamical action was called into play, namely, those in which a circuit, composed of two metals only, became electro-magnetic by heating one part of it. This discovery of thermoelectricity was made by Professor Seebeck of Berlin, in 1822, and prosecuted by various persons; especially by Prof. Cumming b of Cambridge, who, early in 1823, extended the examination of this property to most of the metals, and determined their thermo-electric order.

ciation.

⁴ Phil Traus. 1843. Pt. 11.

⁵ Camb Trans. vol. ii. p. 63 On 3 Results of the Magnetic Asso- the Development of Electro-Magnetion by Heat.

But as these investigations exhibited no new mechanical effects of electromotive forces, they do not now further concern us, and we pass on, at present, to a case in which such forces act in a manner different from any of those already described.

DISCOVERY OF DIAMAGNETISM.

[2nd Ed.] [By the discoveries just related, a cylindrical spiral of wire through which an electric current is passing is identified with a magnet; and the effect of such a spiral is increased by placing in it a core of soft iron. By the use of such a combination under the influence of a voltaic battery, magnets are constructed far more powerful than those which depend upon the permanent magnetism of iron. The electro-magnet employed by Dr. Faraday in some of his experiments would sustain a hundred-weight at either end.

By the use of such magnets Dr. Faraday discovered that, besides iron, nickel and cobalt, which possess magnetism in a high degree, many bodies are magnetic in a slight degree. And he made the further very important discovery, that of those substances which are not magnetic, many, perhaps all, possess an oppoate property, in virtue of which he terms them diamagnetic. The opposition is of this kind; -that magnetic bodies in the form of bars or needles, if free to move, arrange themselves in the axial line joining the poles; diamagnetic bodies under the same circumstances arrange themselves in an equatorial position, perpendicular to the axial line. And this tendency he conceives to be the result of one more general; that whereas magnetic bodies are attracted to the poles of a magnet, diamagnetic bodies are repelled from the poles. The list of diamagnetic bodies includes all kinds of substances; not only metals, as antimony, bismuth, gold, silver, lead, tin, zinc, but many crystals, glass, phosphorus, sulphur, sugar, gum, wood, ivory; and even flesh and fruit.

It appears that M. le Bailli had shown, in 1829, that both bismuth and antimony and bismuth repelled

the magnetic needle; and as Dr. Faraday remarks, it is astonishing that such an experiment should have remained so long without further results. M. Becquerel in 1827 observed, and quoted Coulomb as having also observed, that a needle of wood under certain conditions pointed across the magnetic curves; and also stated that he had found a needle of wood place itself parallel to the wires of a galvanometer. This he referred to a magnetism transverse to the length. But he does not refer the phenomena to elementary repulsive action, nor show that they are common to an immense class of bodies, nor distinguish this diamagnetic from the magnetic class, as Faraday has taught us to do.

I do not dwell upon the peculiar phenomena of copper which, in the same series of researches, are traced by Dr. Faraday to the combined effect of its diamagnetic character, and the electric currents excited in it by the electro-magnet; nor to the optical phenomena manifested by certain transparent diamagnetic substances under electric action; as already stated in Book IX.⁶]

⁶ See the Twentieth Series of Experimental Researches in Electricity, read to the Royal Society, Dec. 18, 1845.

CHAPTER VIII.

DISCOVERY OF THE LAWS OF MAGNETO-ELECTRIC INDUCTION. — FARADAY.

T was clearly established by Ampère, as we have seen, that magnetic action is a peculiar form of electromotive actions, and that, in this kind of agency, action and reaction are equal and opposite. It appeared to follow almost irresistibly from these considerations, that magnetism might be made to produce electricity, as electricity could be made to imitate all the effects of magnetism. Yet for a long time the attempts to obtain such a result were fruitless. Faraday, in 1825, endeavoured to make the conducting-wire of the voltaic circuit excite electricity in a neighbouring wire by induction, as the conductor charged with common electricity would have done, but he obtained no such effect. If this attempt had succeeded, the magnet, which, for all such purposes, is an assemblage of voltaic circuits, might also have been made to excite electricity. About the same time, an experiment was made in France by M. Arago, which really involved the effect thus sought; though this effect was not extricated from the complex phenomenon, till Faraday began his splendid career of discovery on this subject in 1832. Arago's observation was, that the rapid revolution of a conducting-plate in the neighbourhood of a magnet, gave rise to a force acting on the magnet. In England, Messrs. Barlow and Christie, Herschel and Babbage, repeated, and tried to analyse this experiment; but referring the forces only to conditions of space and time, and overlooking the real cause, the electrical currents produced by the motion, these philosophers were altogether unsuccessful in their laboura. In 1831, Faraday again sought for electro-dynamical induction, and after some futile trials, at last found it in a form different from that in which he had looked for it. It was then seen, that at the

precise time of making or breaking the contact which closed the galvanic circuit, a momentary effect was induced in a neighbouring wire, but disappeared instantly 1 Once in possession of this fact, Mr. Faraday ran rapidly up the ladder of discovery, to the general point of view - Instead of suddenly making or breaking the contact of the inducing circuit, a similar effect was produced by removing the inducible wire nearer to or further from the circuit,2—the effects were increased by the proximity of soft iron;3—when the soft iron was affected by an ordinary magnet instead of the voltaic wire, the same effect still recurred; and thus it appeared, that by making and breaking magnetic contact, a momentary electric current was produced. It was produced also by moving the magnet;5-or by moving the wire with reference to the magnet.6 Finally, it was found that the earth might supply the place of a magnet in this as in other experiments; and the mere motion of a wire, under proper circumstances, produced in it, it appeared, a momentary electric current.8 These facts were curiously confirmed by the results in special cases. They explained Arago's experiments; for the momentary effect became permanent by the revolution of the plate. And without using the magnet, a revolving plate became an electrical machine, -a revolving globe exhibited electro-magnetic action, 10 the circuit being complete in the globe itself without the addition of any wire; -and a mere motion of the wire of a galvanometer produced an electro-dynamic effect upon its needle 11

But the question occurs, What is the general law which determines the direction of electric currents thus produced by the joint effects of motion and magnetism? Nothing but a peculiar steadiness and clearness in his conceptions of space, could have en-

Phil. Trans 1832, p. 127, First 7 Second Series, Phil. Trans.
Series, Art to. p. 163.

⁴ Art 37. Art. 39. 10 Art. 164. 11 Art. 171. 5 Art 53.

abled Mr. Faraday to detect the law of this phenomenon. For the question required that he should determine the mutual relations in space which connect the magnetic poles, the position of the wire, the direction of the wire's motion, and the electrical current produced in it. This was no easy problem, indeed, the mere relation of the magnetic to the electric forces, the one set being perpendicular to the other, is of itself sufficient to perplex the mind, as we have seen in the history of the electrodynamical discoveries. But Mr. Faraday appears to have seized at once the law of the phenomena. 'The relation,' he says,12 'which holds between the magnetic pole, the moving wire or metal, and the direction of the current evolved, is very simple so it seemed to him), although rather difficult to express. He represents it by referring position and motion to the 'imagnetic curves,' which go from a nagnetic pole to the opposite pole. The current in the ware sets one way or the other, according to the direction in which the motion of the wire cuts these curves. And thus he was enabled, at the end of his Second Series of Researches (December, 1831), to give, in general terms, the law of nature to which may be referred the extraordinary number of new and curious experiments which he has stated;13-namely, that if a wire move so as to cut a magnetic curve, a power is called into action which tends to urge a magnetic current through the wire; and that if a mass move so that its parts do not move in the same direction across the magnetic curves, and with the same angular velocity, electrical currents are called into play in the BRRIT

This rule, thus simple from its generality, though inevitably complex in every special case, may be looked upon as supplying the first demand of philosophy, the law of the phenomena; and accordingly Dr. Faraday has, in all his subsequent researches on magneto-electric induction, applied this law to his experiments; and has thereby unravelled an immense amount of

¹⁵ First Series, Art. 114.

apparent inconsistency and confusion, for those who have followed him in his mode of conceiving the

subject

But yet other philosophers have regarded these phenomena in other points of view, and have stated the laws of the phenomena in a manner different from Faraday's, although for the most part equivalent to his. And these attempts to express, in the most simple and general form, the law of the phenomena of magneto electrical induction, have naturally been combined with the expression of other laws of electrical and magnetical phenomena. Further, these endeavours to connect and generalize the Facts have naturally been clothed in the garb of various Theories:—the laws of phenomena have been expressed in terms of the supposed causes of the phenomena; as fluids, attractions and repulsions, particles with currents running through them or round them, physical lines of force, and the like. Such views, and the conflict of them, are the natural and hopeful prognostics of a theory which shall barmonize their discords and include all that each contains of Truth. The fermentation at present is perhaps too great to allow us to see clearly the truth which lies at the bottom. But a few of the leading points of recent discussions on these subjects will be noticed in the Additions to this volume.

CHAPTER IX.

TRANSITION TO CHEMICAL SCIENCE.

THE preceding train of generalization may justly L appear extensive, and of itself well worthy of admiration. Yet we are to consider all that has there been established as only one-half of the science to which it belongs, -one limb of the colossal form of Chemistry. We have ascertained, we will suppose, the laws of Electric Polarity; but we have then to ak. What is the relation of this Polarity to Chemical Composition? This was the great problem which, constantly present to the minds of electro-chemical inquirers, drew them on, with the promise of some deep and comprehensive insight into the mechanism of nature. Long tasks of research, though only subeidiary to this, were cheerfully undertaken, Faraday describes himself as compelled to set about satisfying himself of the identity of common, animal, and voltaic electricity, as 'the decision of a doubtful point which interfered with the extension of his views, and destroyed the strictness of reasoning.' Having established this identity, he proceeded with his grand undertaking of electro-chemical research,

The connexion of electrical currents with chemical action, though kept out of sight in the account we have hitherto given, was never forgotten by the experimenters, for, in fact, the modes in which electrical currents were excited, were chemical actions;—the action of acids and metals on each other in the voltaic trough, or in some other form. The dependence of the electrical effect on these chemical actions, and still more, the chemical actions produced by the agency of the poles of the circuit, had been carefully studied;

and we must now relate with what success.

But in what terms shall we present this narration?

¹ Dec. 1832. Researches, 266.

We have spoken of chemical actions,—but what kind of actions are these? Decomposition; the resolution of compounds into their ingredients; the separation of acids from bases, the reduction of bodies to simple elements. These names open to us a new drama; they are words which belong to a different set of relations of things, a different train of scientific inductions, a different system of generalizations, from any with which we have hitherto been concerned. We must learn to understand these phrases, before we can

advance in our history of human knowledge.

And how are we to learn the meaning of this collection of words? In what other language shall it be explained? In what terms shall we define these new expressions? To this we are compelled to reply, that we cannot translate these terms into any ordinary language; - that we cannot define them in any terms already familiar to us. Here, as in all other branches of knowledge, the meaning of words is to be sought in the progress of thought, the history of science is our dictionary; the steps of scientific induction are our definitions. It is only by going back through the successful researches of men respecting the composition and elements of bodies, that we can learn in what sense such terms must be understood, so as to convey real knowledge. In order that they may have a meaning for us, we must inquire what meaning they had in the minds of the authors of our discoveries.

And thus we cannot advance a step, till we have brought up our history of Chemistry to the level of our history of Electricity;—till we have studied the progress of the analytical, as well as the mechanical sciences. We are compelled to pause and look backwards here; just as happened in the history of astronomy, when we arrived at the brink of the great mechanical inductions of Newton, and found that we must trace the history of Mechanics, before we could proceed to mechanical Astronomy. The terms 'force, attraction, inertia, momentum,' sent us back into preceding centuries then, just as the terms 'composition' and 'element' send us back now.

Nor is it to a small extent that we have thus to double back upon our past advance. Next to Astronomy. Chemistry is one of the most ancient of sciences; -the field of the earliest attempts of man to command and understand nature. It has held men for centuries by a kind of fascination; and innumerable and endless are the varied labours, the failures and successes, the speculations and conclusions, the strange pretences and fantastical dreams, of those who have pursued it. eximbit all these, or give any account of them, would be impossible; and for our design, it would not be pertinent. To extract from the mass that which is to our purpose, is difficult; but the attempt must be made. We must endeavour to analyse the history of Chemistry, so far as it has tended towards the establishment of general principles. We shall thus obtain a sight of generalizations of a new kind, and shall prepare ourselves for others of a higher order.

.

BOOK XIV.

THE ANALYTICAL SCIENCE.

HISTORY OF CHEMISTRY.

Opened into the hill a spacious wound,
And digged out ribs of gold
Anon out of the earth a fabric huge
Rose like an exhalation with the sound
Of dulcet symphonies and voices sweet,
Built like a temple.

MILTON. Paradise Lost, i.

CHAPTER L

IMPROVEMENT OF THE NOTION OF CHEMICAL ANA-LYSIS, AND RECOGNITION OF IT AS THE SPACIFIC ART.

THE doctrine of 'the four elements' is one of the L oldest monuments of man's speculative nature: goes back, perhaps, to times anterior to Greek philosophy, and, as the doctrine of Aristotle and Galen, reigned for fifteen hundred years over the Gentile, Christian, and Mohammedan world. In medicine, taught as the doctrine of the four 'elementary qualittes, of which the human body and all other substances are compounded, it had a very powerful and extensive influence upon medical practice. But this doctrine never led to any attempt actually to analyse bodies into their supposed elements, for composition was inferred from the resemblance of the qualities, not from the separate exhibition of the ingredients; the supposed analysis was, in short, a decomposition of the body into adjectives, not into substances.

This doctrine, therefore, may be considered as a negative state, antecedent to the very beginning of chemistry; and some progress beyond this mere negation was made, as soon as men began to endeavour to compound and decompound substances by the use of fire or mixture, however erroneous might be the opinions and expectations which they combined with their attempts. Alchemy is a step in chemistry, so far as it implies the recognition of the work of the cupel and the retort, as the produce of analysis and synthesis. How perplexed and perverted were the forms in which this recognition was clothed,—how mixed up with mystical follies and extravagancies, we have already seen; and the share which Alchemy had in the formation of any sounder knowledge, is not such

as to justify any further notice of that pursuit.

The result of the attempts to analyse bodies by heat, mixture, and the like processes, was the doctrine that the first principles of things are three, not four;

namely, salt, sulphur, and mercury, and that, of these three, all things are compounded. In reality, the doctrine, as thus stated, contained no truth which was of any value; for, though the chemist could extract from most bodies portions which he called salt, and sulphur, and mercury, these names were given, rather to save the hypothesis, than because the substances were really those usually so called; and thus the supposed analyses proved nothing, as Boyle justly urged

against them.1

The only real advance in chemical theory, therefore, which we can ascribe to the school of the three principles. as compared with those who held the ancient dogma of the four elements, is, the acknowledgment of the changes produced by the chemist's operations, as being changes which were to be accounted for by the union and separation of substantial elements, or, as they were sometimes called, of hypostatical principles. The workmen of this school acquired, no doubt, a considerable acquaintance with the results of the kinds of processes which they pursued; they applied their knowledge to the preparation of new medicines; and some of them. as Paracelsus and Van Helmont, attained, in this way. to great fame and distinction: but their merits, as regards theoretical chemistry, consist only in a truer conception of the problem, and of the mode of attempting its solution, than their predecessors had entertained.

This step is well marked by a word which, about the time of which we speak, was introduced to denote the chemist's employment. It was called the Spagiric art, (often misspelt Spagyric,) from two Greek words, (oxáw, dyelow,) which mean, to separate parts, and to unite them. These two processes, or, in more modern language, analysis and synthesis, constitute the whole business of the chemist. We are not making a fanciful arrangement, therefore, when we mark the recognition of this object as a step in the progress of chemistry. I now proceed to consider the manner in which the conditions of this analysis and synthesis were further

developed.

¹ Shaw's Boyle. Skeptical Chymist, pp. 312, 313, &c.

CHAPTER II.

DOCTRINE OF ACID AND ALKALI,-SYLVIUS.

MONG the results of mixture observed by chemists, A were many instances in which two ingredients, each in itself pungent or destructive, being put together, became mild and inoperative; each counteracting and neutralizing the activity of the other. The notion of such opposition and neutrality is applicable to a very wide range of chemical processes. The person who appears first to have steadily seized and generally applied this notion is Francis de la Boé Sylvius; who was born in 1614, and practised medicine at Amsterdam, with a success and reputation which gave great currency to his opinions on that art.1 His chemical theories were propounded as subordinate to his medical doctrines; and from being thus presented under a most important practical aspect, excited far more attention than mere theoretical opinions on the composition of bodies could have done. Sylvius is spoken of by historians of science, as the founder of the intro-chemical ect among physicians; that is, the sect which considers the disorders in the human frame as the effects of chemical relations of the fluids, and applies to them modes of cure founded upon this doctrine. We have here to speak, not of his physiological, but of his chemical, Tiews.

The distinction of acid and alkaline bodies (acidum, lizium) was familiar before the time of Sylvius; but be trained a system, by considering them both as emibently acrid and yet opposite, and by applying this botion to the human frame. Thus? the lymph contains an acid, the bile an alkaline salt. These two opposite acrid substances, when they are brought together,

Byrengel. Geschichte der Areneykunde, vol. iv. Thomson's History of Chemistry in the corresponding part is translated from Sprengel.

^{*} Do Methodo Medendi, Amst. 1679. Lib. ii, cap. 28, sects. 8 and 53.
VOL. III.

neutralize each other (infringunt), and are changed into an intermediate and milder substance

The progress of this doctrine, as a physiological one. is an important part of the history of medical science in the seventeenth century; but with that we are not here But as a chemical doctrine, this notion of the opposition of acid and alkali, and of its very general applicability, struck deep root, and has not been eradicated up to our own time. Boyle, indeed, whose disposition led him to suspect all generalities, expressed doubts with regard to this view;3 and argued that the supposition of acid and alkaline parts in all bodies was precarious, their offices arbitrary, and the notion of them unsettled. Indeed it was not difficult to show, that there was no one certain criterion to which all supposed acids conformed. Yet the general conception of such a combination as that of acid and alkali was supposed to be, served so well to express many chemical facts, that it kept its ground. It is found, for instance. in Lemery's Chemistry, which was one of those in most general use before the introduction of the phlogistic theory. In this work (which was translated into English by Keill, in 1698) we find alkalies defined by their effervescing with acids.4 They were distinguished as the mineral alkali (soda), the vegetable alkali (potassa), and the volatile alkalı (ammonia). Again, in Macquer's Chemistry, which was long the text-book in Europe during the reign of phlogiston, we find acids and alkalies, and their union, in which they rob each other of their characteristic properties, and form neutral salts, stated among the leading principles of the science.

In truth, the mutual relation of acids to alkalies was the most essential part of the knowledge which chemists possessed concerning them. The importance of this relation arose from its being the first distinct form in which the notion of chemical attraction or affinity appeared. For the acrid or caustic character of acids and alkalies is, in fact, a tendency to alter the bodies they

³ Shaw's Boyle, ill. p 432.

⁴ Lemery, p. 25.

Macquer, p. 19.

character of the compounds is the absence of any such proclivity to change. Acids and alkalies have a strong disposition to unite. They combine, often with vehomence, and produce neutral salts, they exhibit, in short, a prominent example of the chemical attraction, or affinity, by which two ingredients are formed into a compound. The relation of acid and base in a salt is, to this day, one of the main grounds of all theoretical reasonings.

The more distinct development of the notion of such chemical attraction, gradually made its way among the chemists of the latter part of the seventeenth and beginning of the eighteenth century, as we may see in the writings of Boyle, Newton, and their followers. Beacher speaks of this attraction as a magnetism, but I do not know that any writer in particular, can be pointed out as the person who firmly established the

general notion of chemical attraction.

But this idea of chemical attraction became both more clear and more extensively applicable, when it assumed the form of the doctrine of elective attractions,

in which shape we must now speak of it,

CHAPTER III.

DOCTRINE OF ELECTIVE ATTRACTIONS.
GEOFFROY. BERGMAN.

HOUGH the chemical combinations of bodies had already been referred to attraction, in a vague and general manner, it was impossible to explain the changes that take place, without supposing the attraction to be greater or less, according to the nature of Yet it was some time before the necessity of such a supposition was clearly seen. In the history of the French Academy for 1718 (pullished 1719), the writer of the introductory notice (probably Fontenelle) says, 'That a body which is united to another, for example, a solvent which has penetrated a metal, should quit it to go and unite itself with another which we present to it, is a thing of which the possibility had never been guessed by the most subtle philosophers, and of which the explanation even now is not easy.' The doctrine had, in fact, been stated by Stahl, but the assertion just quoted shows, at least, that it was not familiar. The principle, however, is very cleared stated in a memoir in the same volume, by Geoffroy, a French physician of great talents and varied knowledge. 'We observe in chemistry,' he says, 'certain relations amongst different bodies, which cause them to unite. These relations have their degrees and their laws. We observe their different degrees in this, -that among different matters jumbled together, which have a certain disposition to unite, we find that one of these substances always unites constantly with a certain other, preferably to all the rest.' He then states that those which unite by preference. have 'plus de rapport,' or, according to a phrase afterwards used, more offinity. 'And I have satisfied myself, he adds, 'that we may deduce, from these

¹ Mém. Acad. Par 1718, p. 202.

loctrine of Elective Attractions, as thus promulnorthined to large a mass of truth, that it was seriously shaken, though it required further ment and correction. In particular the colowork of Torbern Bergman, professor at Upwala,

² Prof , p. 13

On Elective Attractions, published in 1775, introduced into it material improvements. Bergman observed, that not only the order of attractions, but the sum of those attractions which had to form the new compounds, must be taken account of, in order to judge of the result. Thus, if we have a combination of two elements, P, s, (potassa and vitriohe acid,) and another combination, L, m, (time and muriatic acid) though s has a greater affinity for P than for L, yet the sum of the attractions of P to m, and of L to s, is greater than that of the original compounds, and therefore if the two combinations are brought together, the new compounds, P, m, and L, s, are formed.

The Table of Elective Attractions, modified by Bergman in pursuance of these views, and corrected according to the advanced knowledge of the time, became still more important than before. The next step was to take into account the quantities of the elements which combined, but this leads us into a new train of investigation, which was, indeed, a natural sequel

to the researches of Geoffroy and Bergman.

In 1803, however, a chemist of great eminence, Berthollet, published a work (Essar de Statique Chimique), the tengency of which appeared to be to throw the subject back into the condition in which it had been before Geoffroy. For Berthollet maintained that the rules of chemical combination were not definite, and dependent on the nature of the substances alone, but indefinite, depending on the quantity present, and other circumstances. Proust answered him, and as Berzelius says, 4 · Berthollet defended himself with an acuteness which makes the reader hesitate in his judgment; but the great mass of facts finally decided the point in favour of Proust.' Before, however, we trace the result of these researches, we must consider Chemistry as extending her inquiries to combustion as well as mixture, to airs as well as fluids and solids, and to weight as well as quality. These three steps we shall now briefly treat of.

⁴ Chem., t. ili. p. 33.

CHAPTER IV.

DOCTRINE OF ACHIEFICATION AND COMBUSTION, PHLOGISTIC THEORY.

DUBLICATION of the Theory by Beccher and Stabl. It will be recollected that we are tracing the history of the progress only of Chemistry, not of its errours, that we are concerned with doctrines only so far as they are true, and have remained part of the received system of chemical truths. The Phlogastic Theory was deposed and succeeded by the Theory of Oxygen. But this circumstance must not lead us to overlook the really sound and permanent part of the opanions which the founders of the phlogistic theory taught. They brought together, as processes of the same kind, a number of changes which at first appeared to have nothing in common, as acidification, combustion, respiration. Now this classification is true; and its importance remains undiminished, whatever are the explanations which we adopt of the processes themselves.

The two chemists to whom are to be ascribed the ment of this step, and the establishment of the phlogistic theory which they connected with it, are John Joachim Beccher and George Ernest Stahl, the former of whom was professor at Mentz, and physician to the Elector of Bavaria (born 1625, died 1682); the latter was professor at Halle, and afterwards royal physician at Berlin (born 1660, died 1734). These two men, who thus contributed to a common purpose, were very different from each other. The first was a frank and ardent enthusiast in the pursuit of chemistry, who speaks of himself and his employments with a commumicativeness and affection both amusing and engaging. The other was a teacher of great talents and influence, but accused of haughtiness and moroseness, a character which is well borne out by the manner in which, in his writings, he anticipates an unfavourable reception, and defies it. But it is right to add to this, that he speaks of Beccher, his predecessor, with an ungradging acknowledgment of obligations to him, and a vehement assertion of his merit as the founder of the true system, which give a strong impression of Stahl's

justice and magnanimity.

Beecher's opinions were at first promulgated rather as a correction than a refutation of the doctrine of the three principles, salt, sulphur, and mercury. The main peculiarity of his views consists in the offices which he ascribes to his sulphur, these being such as afterwards induced Stahl to give the name of Phlogiston to this element. Beccher had the sagacity to see that the reduction of metals to an earthy form (calr), and the formation of sulphuric acid from sulphur, are operations connected by a general analogy, as being alike processes of combustion. Hence the metal was supposed to consist of an earth, and of something which, in the process of combustion, was separated from it; and, in like manner, sulphur was supposed to consist of the sulphuric acid, which remained after its combustion, and of the combustible part or true sulphur, which flew off in the burning. Beccher jusists very distinctly upon this difference between his element sulphur and the 'sulphur' of his Paracelsian prede-Cessors.

It must be considered as indicating great knowledge and talent in Stahl, that he perceived so clearly what part of the views of Beccher was of general truth and permanent value. Though he' everywhere gives to Beccher the credit of the theoretical opinions which he promulgates, ('Beccheriana sunt quæ profero,') it seems certain that he had the merit, not only of proving them more completely, and applying them more widely than his forerunner, but also of conceiving them with a distinctness which Beccher did not attain. In 1697, appeared Stahl's *Zymotechnia Fundamentalis* (the Doctrine of Fermentation), 'simulque experimentum novum sulphur verum arte producendi.' In this work

¹ Stahl, Prof. ad Specim. Beech. 1703.

(besides other tenets which the author considered as very important) the opinion published by Beccher was now maintained in a very distinct form; -namely, that the process of forming sulphur from sulphuric acid, and of restoring the metals from their calces, are analogous, and consist alike in the addition of some combustible element, which Stahl termed phlogiston (oxograve, combustible). The experiment most insisted on in the work now spoken of, was the formation of sulplur from sulphate of potass (or of soda) by fusing the salt with an alkali, and throwing in coals to supply phlogiston. This is the 'experimentum novum.' Though Stahl published an account of this process, he seems almost to have regretted his openness. 'He denies not,' he says, 'that he should peralventure have dissembled this experiment as the true foundation of the Beccherian assertion concerning the nature of sulphur, if he had not been provoked by the pretending arrogance of some of his contemporaries.

From this time, Stahl's confidence in his theory may be traced becoming more and more settled in his succeeding publications. It is hardly necessary to observe here, that the explanations which his theory gives are easily transformed into those which the more recent theory supplies. According to modern views, the addition of oxygen takes place in the formation of acids and of calces, and in combustion, instead of the subtraction of phiogiston. The coal which Stahl supposed to supply the combustible in his experiment, does in fact absorb the liberated oxygen. In like manner, when an acid corrodes a metal, and, according to the existing theory, combines with and oxidates it, Stahl supposed that the phlogiston separated from the metal and combined with the acid That the explanations of the phlogistic theory are so generally capable of being translated into the oxygen theory, merely by inverting the supposed transfer of the combustible element, shows us how important a step

the so-called Sulphur, in 1718, in which he gave (in German) both an historical and a systematic view of his opinious on the nature of salts and of his

Phlogiston.

Reception and Application of the Theory. - The theory that the formation of sulphuric acid, and the restoration of metals from their calces, are analogous processes, and consist in the addition of phlogiston, was soon widely received; and the Phlogistic School was thus established. From Berlin, its original seat, it was diffused into all parts of Europe. The general reception of the theory may be traced, not only in the use of the term 'phlogiston,' and of the explanations which it implies; but in the adoption of a nomenclature founded on those explanations, which, though not very extensive, is sufficient evidence of the prevalence of the theory. Thus when Priestley, in 1774, discovered oxygen, and when Scheele, a little later, discovered chlorine, these gases were termed dephlogisticated air, and dephlogisticated marine acid; while azotic acid gas, having no disposition to combustion, was supposed to be saturated with phlogiston, and was called phlogisticated air.

This phraseology kept its ground, till it was expelled by the antiphlogistic, or oxygen theory. For instance, Cavendish's papers on the chemistry of the airs are expressed in terms of it, although his researches led him to the confines of the new theory. We must now give an account of such researches, and of the conse-

quent revolution in the science.

CHAPTER V.

CHEMISTRY OF GASES .- BLACK. CAVENDISH.

THE study of the properties of aëriform substances. or Pneumatic Chemistry, as it was called, occupied the chemists of the eighteenth century, and was the main occasion of the great advances which the science made at that period. The most material general truths which came into view in the course of these researches, were, that gases were to be numbered among the constituent elements of solid and fluid bodies; and that, in these, as in all other cases of composition, the compound was equal to the sum of its elements. The latter proposition, indeed, cannot be looked upon as a discovery, for it had been frequently acknowledged, though little applied; in fact, it could not be referred to with any advantage, till the aeriform elements, as well as others, were taken into the account, As soon as this was done, it produced a revolution in chemistry.

[2nd Ed] [Though the view of the mode in which gaseous elements become fixed in bodies and determine their properties, had great additional light thrown upon it by Dr. Black's discoveries, as we shall see, the notion that solid bodies involve such gaseous elements was not new at that period. Mr. Vernon Harcourt has shown! that Newton and Boyle admitted into their speculations airs of various kinds, capable of fixation in bodies. I have, in the succeeding chapter, (Chap. vi.) spoken of the views of Rey, Hooke and Mayow, connected with the function of airs in chemistry, and forming a prelude to the Oxygen

Theory.

Notwithstanding these preludes, the credit of the first great step in pneumatic chemistry is, with justice, assigned to Dr. Black, afterwards professor at Edin-

Phil. Mag. 1846.

burgh, but a young man of the age of twenty-four at the time when he made his discovery. 2 He found that the difference between caustic lime and common limestone arose from this, that the latter substance consists of the former, combined with a certain air, which, being thus fixed in the solid body, he called fixed air (carbonic acid gas) He found, too, that magnesia, caustic potash, and caustic soda, would combine with the same air, with similar results. Thus discovery consisted, of course, in a new interpretation of observed changes. Alkalies appeared to be made caustic by contact with quicklime, at first Black imagined that they underwent this change by acquiring igneous matter from the quicklime; but when he perceived that the lime gained, not lost, in magnitude as it became mild, he rightly supposed that the alkalies were rendered caustic by imparting their air to the lime. This discovery was announced in Black's inaugural dissertation, pronounced in 1755, on the occasion of his taking his degree of Doctor in the University of Edinburgh,

The chemistry of airs was pursued by other experimenters. The Honourable Henry Cavendish, about 1765, invented an apparatus, in which aerial fluids are confined by water, so that they can be managed and examined. This hydro-pneumatic apparatus, or, as it is sometimes called, the pneumatic trough, from that time was one of the most indispensable parts of the chemist's apparatus. Cavendish,3 in 1766, showed the identity of the properties of fixed air derived from various sources; and pointed out the peculiar qualities of inflammable air (afterwards called bydrogen gas), which, being nine times lighter than common air, soon attracted general notice by its employment for raising balloons. The promise of discovery which this subject now offered. attracted the confident and busy mind of Priestley, whose Experiments and Observations on different kinds of Air appeared in 1744 79. In these volumes, he describes an extraordinary number of trials of various kinds; the results of which were, the discovery

Thomson's Hist, Chem. 1, 317.

³ PAH Trans 1706.

of new kinds of air, namely, phlogisticated air (azotic gas) nitrius air (nitrous gas), and dephlogisticated air

(oxygen gas).

But the discovery of new substances, though valuable in supplying chemistry with materials was not so important as discoveries respecting their modes of composition Among such discoveries, that of Cavendish, published in the Philosophical Transactions for 1784. and disclosing the composition of water by the union of two games, oxygen and Lydrogen, must be considered as holding a most distinguished place. He states,4 that 'his experiments were made principally with a view to find out the cause of the dim nution which common air is well known to suffer, by all the various ways in which it is phlogisticated. And, inter describing various unsuccessful attempts, he finds that when juffammable air is used in this phlogistication (or burning), the duminution of the common air is accompanied by the formation of a dew in the apparatua.5 And thus he infers that almost all the inflammable air, and one-fifth of the common air, are turned into pure water.

shall soon see, very important, was employed in a similar attempt at the same time (1783), and had already succeeded? when he learned from Dr. Blagden, who was present at the experiment, that Cavendish had made the discovery a few months sooner. Monge had, about the same time, made the same experiments, and communicated the result to I avoisier and Laplace immediately afterwards. The synthesis was soon confirmed by a corresponding analysis. Indeed the discovery undoubtedly lay in the direct path of chemical research at the time. It was of great consequence in the view it gave of experiments in composition; for the small quantity of water produced in many such processes, had been quite overlooked; though, as it

^{*} Phil Trans 1784, p. 119 * (b=p-128 * 1b. p. 129. 7 A. P. 1281 n. 47s.

now appeared, this water offered the key to the w

interpretation of the change.

Though some objections to Mr. Cavendiah's were offered by Kirwan, on the whole they a generally received with assent and admiration. the bearing of these discoveries upon the new the of Lavoisier, who rejected phiogiston, was so close, we cannot further trace the history of the subject w

out proceeding immediately to that theory.

[2nd Ed.] [I have elsewhere stated, with refere to recent attempts to deprive Cavendish of the or of his discovery of the composition of water, and transfer it to Watt,—that Watt not only did anticipate, but did not fully appreciate the discovery of Cavendish and Lavoisier, and I have expressed concurrence with Mr. Vernon Harcourt's views, whe says, that 'Cavendish pared off from the current hypotheses their theory of combustion, and taffinities of imponderable for ponderable matter complicating chemical with physical consideration and he then corrected and adjusted them with acrable skill to the actual phenomena, not binding facts to the theory, but adapting the theory to the facts

I conceive that the discussion which the subject recently received, has left no doubt on the mind of one who has perused the documents, that Cavendis justly entitled to the honour of this discovery, which has own time was never contested. The publication of his Journals of Experiments¹¹ shows that he ceeded in establishing the point in question in June, 1781. His experiments are referred to in an about of a paper of Priestley's, made by Dr. Maty, secretary of the Royal Society, in June, 1783. June, 1783, also, Dr. Blagden communicated the result of Cavendish's experiments to Lavoisier, at Pawatt's letter, containing his hypothesis that 'we is composed of dephlogisticated air and phlogis

P T. 1784. p. 154. Philosophy, b. vi. c. 4.

¹¹ Appendia to Mr. V. Harcourt's Address.

deprived of part of their latent or elementary heat; and that philogisticated or pure air is composed of water deprived of its philogiston and united to elementary heat and light, was not read till Nov. 1783; and even if it could have suggested such an experiment as Cavendish's (which does not appear likely), is proved, by the dates, to have had no share in doing so.

Mr Cavendish's experiment was suggested by an experiment in which Warltire, a lecturer on chemistry at Birmingham, exploded a mixture of hydrogen and common air in a close vessel, in order to determine

whether heat were pouderable.]

CHAPTER VI.

EPOCH OF THE THEORY OF OXYGEN.- LAVOISIER.

Sect. I .- Prelude to the Theory .- Its Publication.

WE arrive now at a great epoch in the history of Chemistry. Few revolutions in science have immediately excited so much general notice as the introduction of the theory of oxygen. The simplicity and symmetry of the modes of combination which it assumed; and, above all, the construction and universal adoption of a nomenclature which applied to all substances, and which seemed to reveal their immost constitution by their name, naturally gave it an almost irresistible sway over men's minds. We must, however, dispassionately trace the course of its introduction.

Antoine Laurent Lavoisier, an accomplished French chemist, had pursued, with zeal and skill, researches such as those of Black, Cavendish, and Priestley, which we have described above. In 1774, he showed that in the calcination of metals in air, the metal acquires as much weight as the air loses. It might appear that this discovery at once overturned the view which supposed the metal to be phlogiston added to the calk Lavoisier's contemporaries were, however, far from allowing this, a greater mass of argument was needed to bring them to this conclusion. Convincing proofs of the new opinion were, however, rapidly supplied. Thus, when Priestley had discovered dephlogisticated air, in 1774, Lavoisier showed, in 1775, that fixed air consisted of charcoal and the dephlogisticated or pure air; for the mercurial calx which, heated by itself, gives out pure air, gives out, when heated with charcoal, fixed air, which has, therefore, since been called carbonic acid gas.

¹ Mem. Ac. Par. 1775.

Again, Lavoisier showed that the atmospheric air consists of pure or vital air, and of an unvital air, which he thence called azot. The vital air he found to be the agent in combustion, acidification, calcination, respiration; all these processes were analogous; all consisted in a decomposition of the atmospheric air, and a fixation of the pure or vital portion of it.

But he thus arrived at the conclusion, that this pure air was added, in all the cases in which, according to the received theory, philogiston was subtracted, and vice verst. He gave the name² of oxygen (principe oxygens) to 'the substance which thus unites itself with metals to form their calces, and with combustible substances

A new theory was thus produced, which would account for all the facts which the old one would explain, and had besides the evidence of the balance in its favour. But there still remained some apparent objections to be removed. In the action of dilute acids on metals, inflammable air was produced. Whence came this element? The discovery of the decomposition of water sufficiently answered this question, and converted the objection into an argument on the side of the theory: and thus the decomposition of water was, in fact, one of the most critical events for the fortune of the Lavoisierian doctrine, and one which, more than any other, decided chemists in its favour. In succeeding years, Lavoisier showed the consistency of his theory with all that was discovered concerning the composition of alcohol, oil, animal and vegetable substances, and many other bodies.

It is not necessary for us to consider any further the evidence for this theory, but we must record a few circumstances respecting its earlier history. Rey, a French physician, had in 1630, published a book, in which he inquires into the grounds of the increase of the weight of metals by calcination. He says, 'To this question, then, supported on the grounds already mentioned, I answer, and maintain with confidence,

to form acids.

Men. Ac. Par 1781, p. 448.

^{*} Thomson Had Chem. ii, 93.

that the increase of weight arises from the air, which is condensed, rendered heavy and adhesive, by the heat of the furnace.' Hooke and Mayow had entertained the opinion that the air contains a 'nitrous spirit,' which is the supporter of combustion. But Lavoisier disclaimed the charge of having derived anything from these sources; nor is it difficult to understand how the received generalizations of the phlogistic theory had thrown all such narrower explanations into obscurity. The merit of Lavoisier consisted in his combining the generality of Stahl with the verified

conjectures of Rey and Mayow.

No one could have a better claim, by his early enthusiasm for science, his extensive knowledge, and his zealous labours, to hope that a great discovery might fall to his share, than Lavoisier. His father, a man of considerable fortune, had allowed him to make science his only profession; and the zealous philosopher collected about him a number of the most active physical inquirers of his time, who met and experimented at his house one day in the week. In this school, the new chemistry was gradually formed. A few years after the publication of Priestley's first experiments, Lavoisier was struck with the presentiment of the theory which he was afterwards to produce. In 1772, he deposited5 with the secretary of the Academy, a note which contained the germ of his future doctrines. 'At that time,' he says, in explaining this step, 'there was a kind of rivalry between France and England in science, which gave importance to new experiments, and which sometimes was the cause that the writers of the one or other of the nations disputed the discovery with the real author.' In 1777, the editor of the Memoirs of the Academy speaks of his theory as overturning that of Stahl; but the general acceptance of the new opinion did not take place till later.

^{*} Biogr Univ. (Curier.)

h Thomson, il 99.

Sect. 2.—Reception and Confirmation of the Theory of Oxygen.

The Oxygen theory made its way with extraordinary rapidity among the best philosophers. In 1785, that is, soon after Cavendish's synthesis of water had removed some of the most formidable objections to it, Berthollet, already an eminent chemist, declared himself a convert. Indeed it was soon so generally adopted in France, that Fourcroy promulgated its doctrines under the name of 'La Chimie Française,' a title which Lavoisier did not altogether relish. The extraordinary coquence and success of Fourcroy as a lecturer at the Jardin des Plantes, had no small share in the diffusion of the oxygen theory, and the name of 'the apostle of the new chemistry' which was at first given him in ridicule, was justly held by him to be a glorious distinction.

Guyton de Morveau, who had at first been a strenuous advocate of the phlogistic theory, was invited to Paris, and brought over to the opinions of Lavoisier; and soon joined in the formation of the nomenclature founded upon the theory. This step, of which we shall shortly speak, fixed the new doctrine, and diffused it further. Delametherie alone defended the phlogistic theory with vigour, and indeed with violence. He was the editor of the Journal de Physique, and to evade the influence which this gave him, the antiphlogistians established, as the vehicle of their opinions, another periodical, the Annales de Chimie

In England, indeed, their success was not so immediate. Cavendish, in his Memoir of 1784, speaks of the question between the two opinions as doubtful. There are, he says, 'several Memoirs of M. Lavoisier, in which he entirely discards phlogiston, and as not only the foregoing experiments, but most other phenomena of nature, seem explicable as well, or nearly as well, upon this as upon the commonly believed

Thomson, it 130,

⁵ Thomson, iL 133.

⁷ Cuvier, Eloges, i p 20.

⁹ Phil. Truns. 1784, p. 150.

principle of phlogiston, Cavendish proceeds to explain his experiments according to the new views, expressing no decided preference, however, for either system. But Kirwan, another English chemist, contested the point much more resolutely. His theory identified inflammable air, or hydrogen, with phlogiston; and in this view, he wrote a work which was intended as a confutation of the essential part of the oxygen theory. It is a strong proof of the steadiness and clearness with which the advocates of the new system possessed their principles, that they immediately translated this work, adding, at the end of each chapter, a refutation of the phlogistic doctrines which it contained. Lavoisier, Berthollet, De Morveau, Fourcroy, and Monge, were the authors of this curious specimen of scientific polemies. It is also remarkable evidence of the candour of Kirwan, that notwithstanding the prominent part he had taken in the controversy, he allowed himself at last to be convinced. After a struggle of ten years, he wrote 10 to Berthollet in 1796, 'I lay down my arms, and abandon the cause of phlogiston. Black followed the same course. Priestley alone, of all the chemists of great name, would never assent to the new doctrines, though his own discoveries had contributed so much to their establishment, 'He saw,' says Cuvier, 11 ' without flinching, the most skilful defenders of the ancient theory go over to the enemy in succession, and when Kirwan had, almost the last of all, abjured philogiston, Priestley remained alone on the field of battle, and threw out a new challenge, in a memoir addressed to the principal French chemists. It happened, cariously enough, that the challenge was accepted, and the arguments answered by M. Adet, who was at that time (1798.) the French ambassador to the United States, in which country Priestley's work was published Even in Germany, the birthplace and home of the phlogistic theory, the struggle was not long protracted. There was, indeed, a con-

¹⁹ Pref to Foureroy's Chemistry, xiv

¹ Cavier, Elogo de Priestley, p. 208.

troversy, the older philosophers being, as usual, the defenders of the established doctrines, but in 1792, Klaproth repeated, before the Academy of Berlin, all the fundamental experiments, and 'the result was a full conviction on the part of Klaproth and the Academy, that the Lavoisicrian theory was the true one.' 12 Upon the whole, the introduction of the Lavoisicrian theory in the scientific world, when compared with the great revolution of opinion to which it comes nearest in importance, the introduction of the Newtonian theory, shows, by the rapidity and temper with which it took place, a great improvement, both in the means of arriving at truth, and in the spirit with which

they were used.

Some English writers 13 have expressed an opinion that there was little that was original in the new doctrines. But if they were so obvious, what are we to say of emment chemists, as Black and Cavendish, who hesitated when they were presented, or Kirwan and Priestley, who rejected them? This at least shows that it required some peculiar insight to see the evidence of these truths. To say that most of the materials of Lavoinier's theory existed before him, is only to say that his great merit was, that which must always be the great ment of a new theory, his generalization The effect which the publication of his doctrines produced, shows us that he was the first person who, possessing clearly the idea of quantitative composition, applied it steadily to a great range of well ascertained facts. This is, as we have often had to observe, precisely the universal description of an inductive discoverer It has been objected, in like manner, to the originality of Newton's discoveries, that they were contained in those of Kepler. They were so, but they needed a Newton to find them there. The originality of the theory of oxygen is proved by the conflict, short as it was, which accompanied its promulgation; its

¹² Thomson, vol 11 p 136

¹⁵ Brande, Hist Diss in Enc Brit. p 182 Lunn, Chem. in Enc. Met. p. 596.

importance is shown by the changes which it soon

occasioned in every part of the science.

Thus Lavoisier, far more fortunate than most of those who had, in earlier ages, produced revolutions in science, saw his theory accepted by all the most eminent men of his time, and established over a great part of Europe within a few years from its first promulgation. In the common course of events, it might have been expected that the later years of his life would have been spent amid the admiration and reverence which naturally wait upon the patriarch of a new system of acknowledged truths. But the times in which he lived allowed no such euthanasia to eminence of any kind. The democracy which overthrew the ancient political institutions of France, and swept away the nobles of the land, was not, as might have been expected, enthusiastic in its admiration of a great revolution in science, and forward to offer its homage to the genuine nobility of a great discoverer. Lavoisier was thrown into prison on some wretched charge of having, in the discharge of a public office which he held, adulterated certain tobacco; but in reality, for the purpose of confiscating his property.14 In his imprisonment, his philosophy was his resource; and he employed himself in the preparation of his papers for printing. When he was brought before the revolutionary tribunal, he begged for a respite of a few days, in order to complete some researches, the results of which were, he said, important to the good of humanity. The brutish idiot, whom the state of the country at that time had placed in the judgment-seat, told him that the republic wanted no scavans. He was dragged to the guillotine, May the 8th, 1794, and beheaded, in the fifty-second year of his ago, a melancholy proof that, in periods of political ferocity, innocence and merit, private virtues and public services, amiable manners and the love of friends, literary fame and exalted genius, are all as nothing, to protect their

possessor from the last extremes of violence and wrong, indicted under judicial forms.

Sect. 3 .- Nomenclature of the Oxygen Theory.

As we have already said, a powerful instrument in establishing and diffusing the new chemical theory, was a Systematic Nomenclature founded upon it, and applicable to all chemical compounds, which was soon constructed and published by the authors of the theory. Such a nomenclature made its way into general use the more easily, in that the want of such a system had already been severely felt, the names in common use being fantastical, arbitrary, and multiplied beyond measure. The number of known substances had become so great, that a list of names with no regulative principle, founded on accident, caprice and errour, was too cumbrous and inconvenient to be tolerated. Even before the currency which Lavoisier's theory obtained, these evils had led to attempts towards a more convenient set of names. Bergman and Black had constructed such lists, and Guyton de Morveau, a clever and accomplished lawyer of Dijon, had formed a system of nomenclature in 1782, before he had become a convert to Lavoisier's theory, in which task he had been exhorted and encouraged by Bergman and Macquer. In this system, 15 we do not find most of the characters of the method which was afterwards adopted. But a few years later, Lavoisier, De Morveau, Berthollet and Foureroy, associated themselves for the purpose of producing a nomenclature which should correspond to the new theoretical views. This appeared in 1787, and soon made its way into general The main features of this system are, a selection of the simplest radical words, by which substances are designated, and a systematic distribution of terminations, to express their relations. Thus, sulphur, combined with oxygen in two different proportious, forms

La Journal de Physique, 1782, p. 370.

two acids, the sulphurous and the sulphuric; and these acids form, with earthy or alkaline bases, sulphites and sulphates, while sulphur directly combined with another element, forms a sulphuret. The term oxyd (now usually written oxide,) expressed a lower degree of combination with oxygen than the acids. The Méthode de Nomenclature Chimique was published in 1787; and in 1789, Lavoisier published a treatise on chemistry in order further to explain this method. In the preface to this volume, he apologizes for the great amount of the changes, and pleads the authority of Bergman, who had exhorted De Morveau 'to spare no improper names, those who are learned will always be learned, and those who are ignorant will thus learn sooner.' To this maxim they so far conformed, that their system offers few anomalies; and though the progress of discovery, and the consequent changes of theoretical opinions, which have since gone on, appear now to require a further change of nomenclature, it is no small evidence of the skill with which this scheme was arranged, that for half a century it was universally used, and felt to be far more useful and effective than any nomenclature in any science had ever been before.

CHAPTER VII.

APPLICATION AND CORRECTION OF THE OXYGEN THEORY.

CINCE a chemical theory, as far as it is true, must enable us to obtain a true view of the intimate composition of all bodies whatever, it will readily be supposed that the new chemistry led to an immense number of analyses and researches of various kinds. These it is not necessary to dwell upon, nor will I even mention the names of any of the intelligent and diligent men who have laboured in this held. Perhaps one of the most striking of such analyses was Davy's decomposition of the earths and alkalies into metallic bases and oxygen, in 1807 and 1808, thus extending still further that analogy between the earths and the calces of the metals, which had had so large a share in the formation of chemical theories. This discovery, however, both in the means by which it was made, and in the views to which it led, bears upon subjects hereafter to be treated of.

The Lavoisierian theory also, wide as was the range of truth which it embraced, required some limitation and correction. I do not now speak of some erroneous opinions entertained by the author of the theory; as, for instance, that the heat produced in combustion, and even in respiration, arose from the conversion of the oxygen gas to a solid consistence, according to the doctrine of latent heat. Such opinions not being necessarily connected with the general idea of the theory, need not here be considered. But the leading generalization of Lavoisier, that acidification was always combination with oxygen, was found untenable. The point on which the contest on this subject took place was the constitution of the exymuniatic and muriatic acids; as they had been termed by Berthollet, from the belief that murilitie acid contained oxygen, and oxymuriatic a still larger dose of oxygen.

In opposition to this, a new doctrine was put forwards in 1809 by Gay-Lussac and Thenard in France, and by Davy in England;—namely, that oxymuriatic acid was a simple substance, which they termed chlorine, and that muriatic acid was a combination of chlorine with hydrogen, which therefore was called hydrochloric acid—It may be observed, that the point in dispute in the controversy on this subject was nearly the same which had been debated in the course of the establishment of the oxygen theory; namely, whether in the formation of muriatic acid from chlorine, oxygen is subtracted, or hydrogen added, and the water concealed.

In the course of this dispute, it was allowed on both sides, that the combination of dry muriatic acid and ammonia afforded an experimentum crucis; since, if water was produced from these elements, oxygen must have existed in the acid. Davy being at Edinburgh in 1812, this experiment was made in the presence of several eminent philosophers; and the result was found to be, that though a slight dew appeared in the vessel, there was not more than might be ascribed to unavoidable imperfection in the process, and certainly not so much as the old theory of muriatic acid required. The new theory, after this period, obtained a clear superiority in the minds of philosophical chemists, and was further supported by new analogies.¹

For, the existence of one hydracid being thus established, it was found that other substances gave similar combinations; and thus chemists obtained the hydriodic, hydrofluoric, and hydrobromic acids. These acids, it is to be observed, form salts with bases, in the same manner as the oxygen acids do. The analogy of the muriatic and fluoric compounds was first clearly urged by a philosopher who was not peculiarly engaged in chemical research, but who was often distinguished by his rapid and happy generalizations, M. Ampère. He supported this analogy by many ingenious and original arguments, in letters written to Davy, while

Paris, Lefe of Davy, 1, 237.

that chemist was engaged in his researches on fluor

spar, as Davy himself declares.2

Still further changes have been proposed, in that classification of elementary substances to which the oxygen theory led. It has been held by Berzelius and others, that other elements, as, for example, sulphur, form salts with the alkaline and earthy metals, rather than sulphurets. The character of these sulpho-salts, however, is still questioned among chemists; and therefore it does not become us to speak as if their place in history were settled. Of course, it will easily be understood that, in the same manner in which the oxygen theory introduced its own proper nomenclature, the overthrow or material transformation of the theory would require a change in the nomenclature; or rather, the anomalies which tended to disturb the theory, would, as they were detected, make the theoretical terms be felt as inappropriate, and would suggest the necessity of a reformation in that respect But the discussion of this point belongs to a step of the science which is to come before us hereafter.

It may be observed, that in approaching the limits of this part of our subject, as we are now doing, the doctrine of the combination of acids and bases, of which we formerly traced the rise and progress, is still assumed as a fundamental relation by which other relations are tested. This remark connects the stage of chemistry now under our notice with its earliest steps. But in order to point out the chemical bearing of the next subjects of our narrative, we may further observe, that metals, earths, salts, are spoken of as known classes of substances; and in like manner the newly-discovered elements, which form the last trophics of chemistry, have been distributed into such classes according to their analogies; thus potassium, sodium, barium, have been asserted to be metals; iodine, bromine, fluorine, have been arranged as analogical to chlorine. Yet there is something vague and indefinite in the boundaries of such classifications and analogies;

Paris, Life of Davy, I. 370.

and it is precisely where this vagueness falls, that the science is still obscure or doubtful. We are led, therefore, to see the dependence of Chemistry upon Classification; and it is to Sciences of Classification which we shall next proceed; as soon as we have noticed the most general views which have been given of chemical relations, namely, the views of the electrochemists.

But before we do this, we must look back upon a law which obtains in the combination of elements, and which we have hitherto not stated; although it appears, more than any other, to reveal to us the intimate constitution of bodies, and to offer a basis for future generalizations. I speak of the Atomic Theory, as it is usually termed; or, as we might rather call it, the Doctrine of Definite, Reciprocal, and Multiple Proportions.

CHAPTER VIII.

THEORY OF DEFINITE, RECIPROCAL, AND MULTIPLE PROPORTIONS.

Sect. 1.—Prelude to the Atomic Theory, and its Publication by Dalton.

THE general laws of chemical combination announced by Mr Daiton are truths of the highest importance in the science, and are now nowhere contested, but the view of matter as constituted of atoms, which he has employed in conveying those laws, and in expressing his opinion of their cause, is neither so important nor so certain. In the place which I here assign to his discovery, as one of the great events of the history of chemistry, I speak only of the time of phenomena, the rules which govern the quantities in which elements combine.

This law may be considered as consisting of three parts, according to the above description of it,—that elements combine in definite proportions, that these determining proportions operate reciprocally,—and that when, between the same elements, several combining proportions occur, they are related as multiples.

That elements combine in certain definite proportions of quantity, and in no other, was implied, as soon as it was supposed that chemical compounds had any definite properties. Those who first attempted to establish regular formulæ for the constitution of salts, minerals, and other compounds, assumed, as the basis of this process, that the elements in different specimens had the same proportion. Wenzel, in 1777, published his Lehre von der Verwandschaft der Korper, or, Doctone of the Affinities of Bodies, in which he gave many good and accurate analyses. His work, it is said, never grew into general notice. Berthollet, as we have

Thomson, Hist. Chem. vol. ii p. 279.

already stated, maintained that chemical compounds were not definite; but this controversy took place at a later period. It ended in the establishment of the doctrine, that there is, for each combination, only one proportion of the elements, or at most only two or three.

Not only did Wenzel, by his very attempt, presume the first law of chemical composition, the definiteness of the proportions, but he was also led, by his results, to the second rule, that they are reciprocal. For he found that when two neutral salts decompose each other, the resulting salts are also neutral. The neutral character of the salts shows that they are definite compounds; and when the two elements of the one salt, P and s, are presented to those of the other, B and n, if P be in such quantity as to combine definitely with n.

B will also combine definitely with s.2

Views similar to those of Wenzel were also published by Jeremiah Benjamin Richter in 1792, in his Anfangsgrunde der Stochyometrie, oder Messkunst Chymischer Elemente, (Principles of the Measure of Chemical Elements,) in which he took the law, just stated, of reciprocal proportions, as the basis of his researches, and determined the numerical quantities of the common bases and acids which would saturate each other. It is clear that, by these steps, the two first of our three rules may be considered as fully developed. The change of general views which was at this time going on, probably prevented chemists from feeling so much interest as they might have done otherwise, in these details; the French and English chemists, in particular, were fully employed with their own researches and controversies.

Thus the rules which had already been published by Wenzel and Richter had attracted so little notice, that

I am told that Wenzel (whose proposition in a general form, not

book I have not seen), though he use letters in expressing it. adduces many cases in which 2 Thomson, Hist. Chem. vol. ii. double decomposition gives neu- p. 183. tral saits, does not express the

we can hardly consider Mr. Dalton as having been anticipated by those writers, when, in 1803, he began to communicate his views on the chemical constitution of bodies, these views being such as to include both these two rules in their most general form, and further, the rule, at that time still more new to chemists, of multiple proportions. He conceived bodies as composed of atoms of their constituent elements, grouped, either one and one, or one and two, or one and three, and so on. Thus, if C represent an atom of carbon and O one of oxygen, OC will be an atom of carbonic oxide, and OCO an atom of carbonic acid; and hence it follows, that while both these bodies have a definite quantity of oxygen to a given quantity of carbon, in the latter substance this quantity is double of what it is in the former.

The consideration of bodies as consisting of compound atoms, each of these being composed of elementary atoms, naturally led to this law of multiple proportions. In this mode of viewing bodies, Mr. Dalton had been preceded (unknown to himself) by Mr. Higgins, who, in 1789, published his Comparative View of the Phlogistic and Antiphlogistic Theories. He there says,5 'That in volatile vitriolic acid, a single ultimate particle of sulphur is united only to a single particle of dephlogisticated air, and that in perfect vitrolic acid, every single particle of sulphur is united to two of dephlogisticated air, being the quantity necessary to saturation; and he reasons in the same manner concerning the constitution of water, and the compounds of nitrogen and oxygen. These observations of Higgins were, however, made casually, and not followed out, and cannot affect Dalton's claim to original merit.

Mr. Dalton's generalization was first suggested during his examination of olefiant gas and carburetted hydrogen gas; and was asserted generally, on the strength of a few facts, being, as it were, irresistibly

⁴ Turner's Chem. p. 217.

⁶ Thomson, vol. ii. p. 291.

YOL III,

recommended by the clearness and simplicity which the notion possessed. Mr. Dalton himself represented the compound atoms of bodies by symbols, which professed to exhibit the arrangement of the elementary atoms in space as well as their numerical proportion; and he attached great importance to this part of his scheme. It is clear, however, that this part of his doctrine is not essential to that numerical comparison of the law with facts, on which its establishment rests. These hypothetical configurations of atoms have no value till they are confirmed by corresponding facts, such as the optical or crystalline properties of bodies may perhaps one day furnish.

Sect. 2.—Reception and Confirmation of the Atomic Theory.

In order to give a sketch of the progress of the Atomic Theory into general reception, we cannot do better than borrow our information mainly from Dr. Thomson. who was one of the earliest converts and most effective promulgators of the doctrine. Mr. Dalton, at the time when he conceived his theory, was a teacher of mathematics at Manchester, in circumstances which might have been considered narrow, if he himself had been less simple in his manner of life, and less moderate in his worldly views. His experiments were generally made with apparatus of which the simplicity and cheapness corresponded to the rest of his habits. In 1804, he was already in possession of his atomic theory. and explained it to Dr. Thomson, who visited him at that time. It was made known to the chemical world in Dr. Thomson's Chemistry, in 1807; and in Dalton's own System of Chemistry (1808) the leading ideas of it were very briefly stated. Dr. Wollaston's memoir, 'on superacid and subacid salts,' which appeared in the Philosophical Transactions for 1808, did much to secure this theory a place in the estimation of chemista. Here the author states, that he had observed, in various salts, the quantities of acid combined with the base in the neutral and in the superacid salts to be as

one to two: and he says that, thinking it likely this hw might obtain generally in such compounds, it was his design to have pursued the subject, with the hope of discovering the cause to which so regular a relation may be ascribed. But he adds, that this appears to be superfluous after the publication of Dalton's theory by Dr. Thomson, since all such facts are but special cases of the general law. We cannot but remark here, that the scrupulous timidity of Wollaston was probably the only impediment to his anticipating Dalton in the publication of the rule of multiple proportions, and the forwardness to generalize, which belongs to the character of the latter, justly secured him, in this instance, the name of the discoverer of this law. The rest of the English chemists soon followed Wollaston and Thomson, though Davy for some time resisted. They objected, indeed, to Dalton's assumption of atoms; and, to avoid this hypothetical step, Wollaston used the phrase chemical equivalents, and Davy the word proportions, for the numbers which expressed Dalton's stomic weights. We may, however, venture to say that the term 'atom' is the most convenient, and it need not be understood as claiming our assent to the hypothesis of indivisible molecules.

As Wollaston and Dalton were thus arriving independently at the same result in England, other chemists, in other countries, were, unknown to each other, tra-

velling towards the same point.

In 1807, Berzelius, intending to publish a system of chemistry, went through several works little read, and among others the treatises of Richter. He was astonished, he tells us, at the light which was there thrown upon composition and decomposition, and which had never been turned to profit. He was led to a long train of experimental research, and, when he received information of Dalton's ideas concerning multiple proportions, he found, in his own collection of analyses, a full confirmation of this theory.

Some of the Germans, indeed, appear discontented

with the partition of reputation which has taken place with respect to the Theory of Definite Proportions. One⁸ of them says, 'Dalton has only done this;—he has wrapt up the good Richter (whom he knew; compare Schweigger, T, older series, vol. x., p. 381;) in a ragged suit, patched together of atoms; and now poor Richter comes back to his own country in such a garb, like Ulysses, and is not recognized.' It is to be recollected, however, that Richter says nothing of multiple

proportions.

The general doctrine of the atomic theory is now firmly established over the whole of the chemical world. There remain still several controverted points, as, for instance, whether the atomic weights of all elements are exact multiples of the atomic weight of hydrogen. Dr. Prout advanced several instances in which this appeared to be true, and Dr. Thomson has asserted the law to be of universal application. But, on the other hand, Berzelius and Dr. Turner declare that this hypothesis is at variance with the results of the best analyses. Such controverted points do not belong to our history, which treats only of the progress of scientific truths already recognized by all competent judges.

Though Dalton's discovery was soon generally employed, and universally spoken of with admiration, it did not bring to him anything but barren praise, and he continued in the humble employment of which we have spoken, when his fame had filled Europe, and his name become a household word in the laboratory. After some years he was appointed a corresponding member of the Institute of France, which may be considered as a European recognition of the importance of what he had done; and, in 1826, two medals for the encouragement of science having been placed at the disposal of the Royal Society by the King of England, one of them was assigned to Dalton, for his development of the atomic theory. In 1833, at the meeting of the British Association for the Advance-

Mark. Gerch. der Cryst p. 202.

ment of Science, which was held in Cambridge, it was announced that the King had bestowed upon him a pension of 150l., at the preceding meeting at Oxford, that university had conferred upon him the degree of Doctor of Laws, a step the more remarkable, since he belonged to the sect of Quakers. At all the meetings of the British Association he has been present, and bas always been surrounded by the reverence and admiration of all who feel any sympathy with the progress of science. May he long remain among us thus to remind us of the vast advance which Chemistry owes to him!

[2nd Ed.] [Soon after I wrote these expressions of hope, the period of Dalton's sojourn among us terminated. He died on the 27th of July, 1844, aged 78.

His fellow-townsmen, the inhabitants of Manchester, who had so long taken a pride in his residence among them, soon after his death came to a determination to perpetuate his memory by establishing in his honour a Professor of Chemistry at Manchester.

Sect. 3 .- The Theory of Volumes. - Gay-Lussac.

THE atomic theory, at the very epoch of its introduction into France, received a modification in virtue of a curious discovery then made. Soon after the publication of Dalton's system, Gay-Lussac and Humboldt found a rule for the combination of substances, which includes that of Dalton as far as it goes, but extends to combinations of gases only. This law is the theory of volumes; namely, that gases unite together by volume in very simple and definite proportions. Thus water is composed exactly of 100 measures of oxygen and 200 measures of hydrogen. And since these simple ratios 1 and 1, 1 and 2, 1 and 3, alone prevail in such combinations, it may easily be shown that laws like Dalton's law of multiple proportions, must obtain in such cases as he considered.

[2nd Ed.] [M. Schröder, of Mannheim, has endeavoured to extend to solids a law in some degree resembling Gay-Lussac's law of the volumes of gases. According to him, the volumes of the chemical equivalents of simple substances and their compounds are as whole numbers. MM. Kopp, Playfair, and Joule

have laboured in the same field.

I cannot now attempt to trace other bearings and developments of this remarkable discovery. I hasten on to the last generalization of chemistry; which presents to us chemical forces under a new aspect, and brings us back to the point from which we departed in commencing the history of this science.

Die wolecular-volume der Chemischen Verbindungen in festen und flesingen Zustande, 1843.

CHAPTER IX.

RECORD OF DAYY AND FARADAT.

Sect. 1.—Promulgation of the Electro-chemical Theory by Ducy.

THE reader will recollect that the History of Chemistry, though highly important and instructive in itself, has been an interruption of the History of Electro-dynamic Research—a necessary interruption, however, for till we became acquainted with Chemistry in general, we could not follow the course of Electro-chemistry, we could not estimate its vast yet pulloophical theories, nor even express the amplest facts. We have now to endeavour to show what has thus been done, and by what steps,—to give a fitting view of the Epoch of Davy and Faraday.

This is doubtless, a task of difficulty and delicacy. We cannot execute it at all, except we suppose that the great truths, of which the discovery marks this epoch, have already assumed their definite and permasent form. For we do not learn the just value and right place of imperfect attempts and partial advances in science, except by seeing to what they lead. We judge properly of our traits and guesses only when we have gained our point and guessed rightly. We might personify philosophical theories, and might represent them to ourselves as figures, all pressing eagerly onwards in the same direction, whom we have to pursue and it is only in proportion as we ourselves evertake those figures in the race, and pass beyond them, that we are enabled to look back upon their faces; to discern their real aspects, and to catch the true character of their countenances. Except, therefore. I were of opinion that the great truths which Davy brought into aight have been firmly established and clearly developed by Faraday, I could not pretend to give the history of this striking portion of science. But I trust, by the view I have to offer of these beautiful trains of research and their result, to justify the

assumption on which I thus proceed.

I must, however, state, as a further appeal to the render's indulgence, that, even if the great principles of electro-chemistry have now been brought out in their due form and extent, the discovery is but a very few years, I might rather say a few months, old and that this novelty adds materially to the difficulty of estimating previous attempts from the point of view to which we are thus led It is only slowly and by degrees that the mind becomes sufficiently imbued with those new truths, of which the office is, to change the face of a science. We have to consider familiar appearances under a new aspect; to refer old facts to new principles; and it is not till after some time, that the struggle and hesitation which this employment occasions, subsides into a tranquil equilibrium. In the newly-acquired provinces of man's intellectual empire, the din and confusion of conquest pass only gradually into quiet and security. We have seen, in the history of all capital discoveries, how hardly they have made their way, even among the most intelligent and candid philosophers of the antecedent schools: we must, therefore, not expect that the metamorphosis of the theoretical views of chemistry which is now going on, will be effected without some trouble and delay.

I shall endeavour to diminish the difficulties of my undertaking, by presenting the earlier investigations in the department of which I have now to speak, as much as possible according to the most deliberate view taken of them by the great discoverers themselves, Davy and Faraday; since these philosophers are they who have taught us the true import of such investi-

gations.

There is a further difficulty in my task, to which I might refer;—the difficulty of speaking, without errour and without offence, of men now alive, or who were lately members of social circles which exist still around

play a part, is so important to my purpose, that I do not hesitate to incur the responsibility which the narration involves, and I have endeavoured, carnestly, and I hope not in vain, to speak as if I were removed

by centuries from the personages of my story.

The phenomena observed in the Voltaic apparatus were naturally the subject of many speculations as to their cause, and thus gave rise to 'Theories of the Pile.' Among these phenomena there was one class which led to most important results. it was discovered by Nicholson and Carlisle, in 1800, that water was decomposed by the pile of Volta; that is, it was found that when the wires of the pile were placed with their ends near each other in the fluid, a stream of bubbles of air arose from each wire, and these airs were found on examination to be oxygen and hydrogen; which, as we have had to narrate, had already been found to be the constituents of water. This was, as Davy says,1 the true origin of all that has been done in electrochemical science. It was found that other substances also suffered a like decomposition under the same circomstances. Certain metallic solutions were decomposed, and an alkali was separated on the negative plates of the apparatus. Cruickshank, in pursuing these experiments, added to them many important new results, such as the decomposition of muriates of magnesia, soda, and ammonia by the pile; and the general observation that the alkaline matter always appeared at the negative, and the acid at the positive, pole.

Such was the state of the subject when one who was destined to do so much for its advance, first contributed his labours to it. Humphry Davy was a young man who had been apprenticed to a surgeon at Penzance, and having shown an ardent love and a strong aptitude for chemical research, was, in 1798, made the superintendent of a 'Pneumatic Institution,' established at Bristol by Dr. Beddoes, for the purpose of discovering medical powers of factitious airs.' But his main

¹ Phil. Trans. 1816, p. 386.

^{*} Paris, Life of Davy, 1. 58.

attention was soon drawn to galvanism; and when, in consequence of the reputation he had acquired, he was, in 1801, appointed lecturer at the Royal Institution in London, (then recently established,) he was soon put in possession of a galvanic apparatus of great power, and with this he was not long in obtaining the most striking results.

His first paper on the subject is sent from Bristol, in September, 1800, and describes experiments, in which he had found that the decompositions observed by Nicholson and Carlisle go on, although the water, or other substance in which the two wires are plunged, be separated into two portions, provided these portions are connected by muscular or other fibres. This use of muscular fibres was, probably, a remnant of the original disposition, or accident, by which galvanism had been connected with physiology, as much as with chemistry. Davy, however, soon went on towards the conclusion, that the phenomens were altogether chemical in their nature. He had already conjectured. in 1802, that all decompositions might be polar; that is, that in all cases of chemical decomposition, the elements might be related to each other as electrically positive and negative; a thought which it was the peculiar glory of his school to confirm and place in a distinct light. At this period such a view was far from obvious; and it was contended by many, on the contrary, that the elements which the voltaic apparatus brought to view, were not liberated from combinations, but generated. In 1806, Davy attempted the solution. of this question; he showed that the ingredients which had been supposed to be produced by electricity, were due to impurities in the water, or to the decomposition of the vessels; and thus removed all preliminary difficulties. And then, as he says, referring to my experiments of 1800, 1801, and 1802, and to a number of new facts, which showed that inflammable substances and oxygen, alkalies and acids, and oxidable and noble

³ Nicholson's Journal, 4to. iv. 275.

⁴ Phil. Trans 1816.

f 1b. 1826, p. 389.

metals, were in electrical relations of positive and negative, I drew the conclusion, that the combinations and decompositions by electricity were referrible to the law of electrical attractions and repulsions,' and advanced the hypothesis, 'that chemical and electrical attractions were produced by the same cause, acting in the one case on particles, in the other on masses, ... and that the same property, under different modifications, was the cause of all the phenomena exhibited by different

voltaic combinations.'

Although this is the enunciation, in tolerably precise terms, of the great discovery of this epoch, it was, at the period of which we speak, conjectured rather than proved; and we shall find that neither Davy nor his followers, for a considerable period, apprehended it with that distinctness which makes a discovery complete. But in a very short time afterwards, Davy drew great additional notice to his researches by effecting, in pursuance, as it appeared, of his theoretical views, the decomposition of potassa into a metallic base and oxygen. This was, as he truly said, in the memorandum written in his journal at the instant, 'a capital experiment.' This discovery was soon followed by that of the decomposition of soda; and shortly after, of other bodies of the same kind; and the interest and activity of the whole chemical world were turned to the subject in an intense degree.

At this period, there might be noticed three great branches of speculation on this subject; the theory of the pile, the theory of electrical decomposition, and the theory of the identity of chemical and electrical forces; which last doctrine, however, was found to include the other two, as might have been anticipated from

the time of its first suggestion.

It will not be necessary to say much on the theories of the voltaic pile, as separate from other parts of the The contact-theory, which ascribed the action to the contact of different metals, was maintained by Volta himself, but gradually disappeared, as it was

proved (by Wollaston⁶ especially,) that the effect of the pile was inseparably connected with oxidation or other chemical changes. The theories of electrochemical decomposition were numerous, and especially after the promulgation of Davy's Memoir in 1806; and, whatever might be the defects under which these speculations for a long time laboured, the subject was powerfully urged on in the direction in which truth lay, by Davy's discoveries and views. That there remained something still to be done, in order to give full evidence and consistency to the theory, appears from this, that some of the most important parts of Davy's results struck his followers as extraordinary paradoxes ;- for instance, the fact that the decomposed elements are transferred from one part of the circuit to another, in a form which escapes the cognizance of our senses, through intervening substances for which they have a strong affinity. It was found afterwards that the circumstance which appeared to make the process so wonderful, was, in fact, the condition of its going on at all. Davy's expressions often seem to indicate the most exact notions: for instance, he says, 'It is very natural to suppose that the repellent and attractive energies are communicated from one particle to another of the same kind, so as to establish a conducting chain in the fluid, and that the locomotion takes place in consequence;'? and yet at other times he speaks of the elements as attracted and repelled by the metallic surfaces which form the poles; -a different, and, as it appeared afterwards, an untenable view. Mr. Faraday, who supplied what was wanting, justly notices this vagueness. He says, that though, in Davy's celebrated Memoir of 1806, the points established are of the utmost value, 'the mode of action by which the effects take place is stated very generally; so generally, indeed, that probably a dozen precise schemes of electro-chemical action might be drawn up, differing essentially from each other, yet all agreeing with the statement

⁶ Phil. Trans 1801, p. 427.

there given.' And at a period a little later, being reproached by Davy's brother with injustice in this expression, he substantiated his assertion by an enumeration of twelve such schemes which had been

published.

But yet we cannot look upon this Memoir of 1806, otherwise than as a great event, perhaps the most important event of the epoch now under review. And as such it was recognized at once all over Europe. In particular, it received the distinguished honour of being crowned by the Institute of France, although that country and England were then engaged in hierce hostility. Buonaparte had proposed a prize of sixty thousand francs 'to the person who by his experiments and discoveries should advance the knowledge of electricity and galvanism, as much as Franklin and Volta did;' and 'of three thousand francs for the best experiment which should be made in the course of each year on the galvanic fluid;' the latter prize was, by the First Class of the Institute, awarded to Davy.

From this period he rose rapidly to honours and distinctions, and reached a height of scientific fame as great as has ever fallen to the lot of a discoverer in so short a time. I shall not, however, dwell on such circumstances, but confine myself to the progress of my

subject.

Sect. 2.—Establishment of the Electro-chemical Theory by Faraday.

The defects of Davy's theoretical views will be seen most clearly by explaining what Faraday added to them. Michael Faraday was in every way fitted and led to become Davy's successor in his great career of discovery. In 1812, being then a bookseller's apprentice, he attended the lectures of Davy, which at that period excited the highest admiration. My desire to escape from trade, Mr. Faraday says, 'which I thought vicious and selfish, and to enter into the service of science, which I imagined made its pursuers.

amiable and liberal, induced me at last to take the bold and simple step of writing to Sir H. Davy.' He was favourably received, and, in the next year, became Davy's assistant at the Institution; and afterwards his successor. The Institution which produced such researches as those of these two men, may well be considered as a great school of exact and philosophical chemistry. Mr. Faraday, from the beginning of his course of inquiry, appears to have had the consciousness that he was engaged on a great connected work. His Experimental Researches, which appeared in a series of Memoirs in the Philosophical Transactions, are divided into short paragraphs, numbered in a continued order from 1 up to 1160, at the time at which I write; 10 and destined, probably, to extend much further. These paragraphs are connected by a very rigorous method of investigation and reasoning which runs through the whole body of them Yet this unity of purpose was not at first obvious. His first two Memoirs were upon subjects which we have already treated of (B. xiii. c. 5 and c. 8), Voltaic Induction, and the evolution of Electricity from Magnetism. His 'Third Series' has also been already referred to. Its object was, as a preparatory step towards further investigation, to show the identity of voltaic and animal electricity with that of the electrical machine: and as machine electricity differs from the other kinds in being successively in a state of tension and explosion, instead of a continued current, Mr. Faraday succeeded in identifying it with them, by causing the electrical discharge to pass through a bad conductor into a discharging-train of vast extent; nothing less, indeed. than the whole fabric of the metallic gas-pipes and water-pipes of London. In this Memoir 11 it is easy to see already traces of the general theoretical views at which he had arrived; but these are not expressly

December, 1835. (At pre-lished the 'Twenty-first Series' sent, when I am revising the of his Researches ending with second edition, September, 1846, paragraph 2453.)

Dr. Faraday has recently pub-

stated till his 'Fifth Series?' his intermediate Fourth Series being occupied by another subsidiary labour on the conditions of conduction. At length, however, in the Fifth Series, which was read to the Royal Society in June, 1833, he approaches the theory of electro-chemical decomposition. Most preceding theorists, and Davy amongst the number, had referred this result to attractive powers residing in the poles of the apparatus; and had even pretended to compare the intensity of this attraction at different distances from the poles. By a number of singularly beautiful and skilful experiments, Mr. Faraday shows that the phenomena can with no propriety be ascribed to the attraction of the poles.12 'As the substances evolved in cases of electro-chemical decomposition may be made to appear against air,15 which, according to common language, is not a conductor, nor is decomposed; or against water,14 which is a conductor, and can be decomposed; as well as against the metal poles, which are excellent conductors, but undecompossible; there appears but little reason to consider this phenomenon generally as due to the attraction or attractive powers of the latter, when used in the ordinary way, since similar attractions can hardly be imagined in the former instances.'

Faraday's opinion, and, indeed, the only way of expressing the results of his experiments, was, that the chemical elements, in obedience to the direction of the voltaic currents established in the decomposing substance, were evolved, or, as he prefers to say, ejected at its extremities. He afterwards states that the influence which is present in the electric current may be described to as an axis of power, having [at each point] contrary forces exactly equal in amount in

contrary directions.

Having arrived at this point, Faraday rightly wished to reject the term poles, and other words which could hardly be used without suggesting doctrines now

¹³ Researches, Art. 497. 13 Researches, Arts. 465, 469
14 495. 14 517.

proved to be erroneous. He considered, in the case of bodies electrically decomposed, or, as he termed them, electrolytes, the elements as travelling in two opposite directions; which, with reference to the direction of terrestrial magnetism, might be considered as naturally east and west; and he conceived elements as, in this way, arriving at the doors or outlets at which they finally made their separate appearance. The doors he called electrodes, and, separately, the anode and the cathode, 17 and the elements which thus travel he termed the anion and the cation (or cathion).18 By means of this nomenclature he was able to express his general results with much more distinctness and

facility. But this general view of the electrolytical process required to be pursued further, in order to explain the nature of the action. The identity of electrical and chemical forces, which had been hazarded as a conjecture by Davy, and adopted as the basis of chemistry by Berzelius, could only be established by exact measures and rigorous proofs. Faraday had, in his proof of the identity of voltaic and electric agency, attempted also to devise such a measure as should give him a comparison of their quantity; and in this way he proved that 19 a voltaic group of two small wires of platinum and zinc, placed near each other, and immersed in dilute acid for three seconds, yields as much electricity as the electrical battery, charged by ten turns of a large machine; and this was established both by its momentary electro-magnetic effect, and by the amount of its chemical action.20

It was in his 'Seventh Series,' that he finally established a principle of definite measurement of the amount of electrolytical action, and described an instrument which he termed it a volta-electrometer.

¹⁷ Art. 663.

derivation requires calion, but to prefer cathion. make the relation to cathode obvious to the English reader, and

¹⁹ Art. 371.

²⁰ Researches, Art. 537.

this instrument, the amount of action was measured by the quantity of water decomposed and it was necessary, in order to give validity to the mensuration, to show (as Faraday did show) that neither the size of the electrodes, nor the intensity of the current, nor the strength of the acid solution which acted on the plates of the pile, disturbed the accuracy of this measure. He proved, by experiments upon a great variety of substances, of the most different kinds, that the electro-chemical action is definite in amount according to the measurement of the new instrument.22 He had already, at an earlier period, 23 asserted, that the chemical power of a current of electricity is in direct proportion to the absolute quantity of electricity which passes, but the volta-electrometer enabled him to fix with more precision the meaning of this general proposition, as well as to place it beyond doubt.

The vast importance of this step in chemistry soon came into view. By the use of the volta-electrometer, Faraday obtained, for each elementary substance, a number which represented the relative amount of its decomposition, and which might properly be called its 'electro-chemical equivalent.' And the question naturally occurs, whether these numbers bore any relation to any previously established chemical measures. The answer is remarkable. They were no other than the atomic weights of the Daltonian theory, which formed the climax of the previous ascent of chemistry; and thus here, as everywhere in the progress of science, the generalizations of one generation are absorbed in

the wider generalizations of the next.

But in order to reach securely this wider generalization. Faraday combined the two branches of the subject which we have already noticed,—the theory of electrical decomposition with the theory of the pile. For his researches on the origin of activity of the voltaic circuit (his Eighth Series), led him to see more clearly than any one before him, what, as we have said, the most sagacious of preceding philosophers had main.

tained, that the current in the pile was due to the mutual chemical action of its elements. He was led to consider the processes which go on in the excitingcell, and in the decomposing place, as of the same kind, but opposite in direction. The chemical composition of the fluid with the zanc, in the common apparatus, produces, when the circuit is completed, a current of electric influence in the wire; and this current, if it pass through an electrolyte, manifests itself by decomposition, overcoming the chemical affinity which there resists it. An electrolyte cannot conduct without being decomposed. The forces at the point of composition and the point of decomposition are of the same kind, and are opposed to each other by means of the conducting-wire; the wire may properly be spoken of 25 as conducting chemical affinity: it allows two forces of the same kind to oppose one another; 26 electricity is only another mode of the exertion of chemical forces; 27 and we might express all the circumstances of the voltaic pile without using any other term than chemical affinity, though that of electricity may be very convenient.28 Bodies are held together by a definite power, which, when it ceases to discharge that office, may be thrown into the condition of an electric current. 29

Thus the great principle of the identity of electrical and chemical action was completely established. It was, as Faraday, with great candour says, a confirmation of the general views put forth by Davy, in 1806, and might be expressed in his terms, that 'chemical and electrical attractions are produced by the same cause;' but it is easy to see that neither was the full import of these expressions understood, nor were the quantities to which they refer conceived as measureable quantities, nor was the assertion anything but a sagacious conjecture, till Faraday gave the interpretation, measure, and proof, of which we have spoken. The evidence of the incompleteness of the views of his

M Arf. 918.

^{28 917.}

²⁹ BSS.

^{30 965.}

predecessor we have already adduced, in speaking of his vague and inconsistent theoretical account of decomposition. The confirmation of Davy's discoveries by Faraday is of the nature of Newton's confirmation of the views of Borelli and Hooke respecting gravity, or like Young's confirmation of the undulatory theory

of Huyghens.

We must not omit to repeat here the moral which we wish to draw from all great discoveries, that they depend upon the combination of exact facts with clear ideas. The former of these conditions is easily illustrated in the case of Davy and Faraday, both admirable and delicate experimenters. Davy's rapidity and resource in experimenting were extraordinary,31 and extreme elegance and ingenuity distinguish almost every process of Faraday. He had published, in 1829, work on Chemical Munipulation, in which directions are given for performing in the neatest manner all chemical processes. Manipulation, as he there truly mys, is to the chemist like the external senses to the mind, 32 and without the supply of fit materials which such senses only can give, the mind can acquire no real mowledge.

But still the operations of the mind as well as the information of the senses, ideas as well as facts, are requisite for the attainment of any knowledge, and all great steps in science require a peculiar distinctness and vividuess of thought in the discoverer. This it is difficult to exemplify in any better way than by the discoveries themselves. Both Davy and Faraday possessed this vividness of mind, and it was a consequence of this endowment, that Davy's lectures upon chemistry, and Faraday's upon almost any subject of physical philosophy, were of the most bulliant and captivating character. In discovering the nature of voltage action, the essential intellectual requisite was to have a distinct conception of that which Faraday expressed by the remarkable phrase,33 'an axis of power having equal and opposite forces.' and the distinctness of this idea

in Faraday's mind shines forth in every part of his writings. Thus he says, the force which determines the decomposition of a body is in the body, not in the poles. 34 But for the most part he can of course only convey this fundamental idea by illustrations. Thus 36 he represents the voltage circuit by a double circle, studded with the elements of the circuit, and shows how the anions travel round it in one direction, and the cathrons in the opposite. He considers 6 the powers at the two places of action as balancing against each other through the medium of the conductors, in a manner analogous to that in which mechanical forces are balanced against each other by the intervention of the lever. It is impossible to him 37 to resist the idea. that the voltage current must be preceded by a state of tension in its interrupted condition, which is relieved when the circuit is completed. He appears to possess the idea of this kind of force with the same eminent distinctness with which Archimedes in the ancient. and Stevinus in the modern history of science, possessed the idea of pressure, and were thus able to found the science of mechanics.38 And when he cannot obtain these distinct modes of conception, he is dissatisfied, and conscious of defect. Thus in the relation between magnetism and electricity, "9 'there appears to be a link in the chain of effects, a wheel in the physical mechanism of the action, as yet unrecognized ' All this variety of expression shows how deeply seated is the thought. This conception of Chemical Affinity as a peculiar influence or force, which, acting in opposite directions, combines and resolves bodies; -which may be liberated and thrown into the form of a voltaic current, and thus be transferred to remote points. and applied in various ways, -is essential to the understanding, as it was to the making, of these discoveries.

By those to whom this conception has been conveyed, I venture to trust that I shall be held to have given a

³⁴ Art. 661.

²⁶ gs.

^{26 917.}

^{¥7 950.}

faithful account of this important event in the history of science. We may, before we quit the subject, notice one or two of the remarkable subordinate features of Faraday's discoveries.

Sect. 3. - Consequences of Faraday's Discoveries.

FARADAY'S volta-electrometer, in conjunction with the method he had already employed, as we have seen, for the comparison of voltage and common electricity, enabled him to measure the actual quantity of electricity which is exhibited, in given cases, in the form of chemical affinity. His results appeared in numbers of that enormous amount which so often comes before us in the expression of natural laws. One grain of water will require for its decomposition as much electricity as would make a powerful tlash of lightning. By further calculation, he finds this quantity to be not less than 800,000 charges of his Leyden battery, " and this is, by his theory of the identity of the combining with the decomposing force, the quantity of electricity which is naturally associated with the elements of the grain of water, endowing them with their mutual affinity.

Many of the subordicate facts and laws which were brought to light by these researches, clearly point to generalizations, not included in that which we have had to consider, and not yet discovered: such laws do not properly belong to our main plan, which is to make our way up to the generalizations. But there is one which so evidently promises to have an important bearing on future chemical theories, that I will briefly mention it. The class of bodies which are capable of electrical decomposition is limited by a very remarkable law: they are such binary compounds only as consist of single proportionals of their elementary principles. It does not belong to us here to speculate on the possible import of this curious law, which, if not fully established, Faraday has rendered, at least, highly probable: 42 but it is impossible not to see how closely it

connects the Atomic with the Electro-chemical Theory; and in the connexion of these two great members of Chemistry, is involved the prospect of its reaching wider generalizations, and principles more profound

than we have yet caught sight of.

As another example of this connexion, I will, finally, notice that Faraday has employed his discoveries in order to decide, in some doubtful cases, what is the true chemical equivalent; 43 'I have such conviction, he says, 'that the power which governs electro-decomposition and ordinary chemical attractions is the same; and such confidence in the overruling influence of those natural laws which render the former definite. as to feel no hesitation in believing that the latter must submit to them too. Such being the case, I can have no doubt that, assuming hydrogen as I, and dismissing small fractions for the simplicity of expression, the equivalent number or atomic weight of oxygen is 8, of chlorine 36, of bromine 78:4, of lead 103:5, of tin 50, dc.; notwithstanding that a very high authority doubles several of these numbers.'

Sect. 4.—Reception of the Electro-chemical Theory.

THE epoch of establishment of the electro-chemical theory, like other great scientific epochs, must have its sequel, the period of its reception and confirmation, application and extension. In that period we are living, and it must be the task of future historians to trace its course.

We may, however, say a word on the reception which the theory met with, in the forms which it assumed, anterior to the labours of Faraday. Even before the great discovery of Davy, Grotthuss, in 1805, had written upon the theory of electro-chemical decomposition, but he and, as we have seen, Davy, and afterwards other writers, as Riffault and Chompré, in

1807, referred the effects to the poles.44 But the most important attempt to appropriate and employ the generalization which these discoveries suggested, was that of Berzelius; who adopted at once the view of the identity, or at least the universal connexion, of electrical relations with chemical affinity. He considered, 45 that in all chemical combinations the elements may be considered as electro-positive and electro-negative; and made this opposition the basis of his chemical doctrines, in which he was followed by a large body of the chemists of Germany. He held too that the best and light, evolved during cases of powerful combination, are the consequence of the electric discharge which is at that moment taking place: a conjecture which Faraday at first spoke of with praise.46 But at a later period he more sagely says, 47 that the flame which is produced in such cases exhibits but a small portion of the electric power which really acts. 'These therefore may not, cannot, be taken as evidences of the nature of the action; but are merely incidental results, incomparably small in relation to the forces concerned, and supplying no information of the way in which the particles are active on each other, or in which their forces are finally arranged.' And comparing the evidence which he bimself had given of the principle on which Berzeltus's speculations rested, with the speculations themselves, Faraday justly conceived, that he had transferred the doctrine from the domain of what he calls doubtful knowledge, to that of inductive certainty.

Now that we are arrived at the starting-place, from which this well proved truth, the identity of electric and chemical forces, must make its future advances, it would be trifling to dwell longer on the details of the diffusion of that doubtful knowledge which preceded this more certain science. Our history

⁴⁴ Faraday (Researches, Art. 481, 492).

of chemistry is, therefore, here at an end. I have, as far as I could, executed my task; which was, to mark all the great steps of its advance, from the most unconnected facts and the most imperfect speculations, to the highest generalization at which chemical philosophers have yet arrived.

Yet it will appear to our purpose to say a few words on the connexion of this science with those of which we are next to treat; and that I now proceed

to do.

CHAPTER X.

TRANSITION PROM THE CHEMICAL TO THE CLASSIFI-CATORY SCIENCES.

IT is the object and the boast of chemistry to acquire a knowledge of bodies which is more exact and constant than any knowledge borrowed from their sensible qualities can be; since it penetrates into their intimate constitution, and discloses to us the invariable laws of their composition. But yet it will be seen, on a little reflection, that such knowledge could not have any existence, if we were not also attentive to their

sensible qualities.

The whole fabric of chemistry rests, even at the present day, upon the opposition of acids and bases: an acid was certainly at first known by its sensible qualities, and how otherwise, even now, do we perceive its quality? It was a great discovery of modern times that earths and alkalies have for their bases metals: but what are metals? or how, except from lustre, hardness, weight, and the like, do we recognize a body as a metal? And how, except by such characters, even before its analysis, was it known to be an earth or an alkali? We must suppose some classification established, before we can make any advance by experiment or observation.

It is easy to see that all attempts to avoid this difficulty by referring to processes and analogies, as well as to substances, bring us back to the same point in a circle of fallacies. If we say that an acid and alkali are known by combining with each other, we still must ask, What is the criterion that they have combined? If we say that the distinctive qualities of metals and earths are, that metals become earths by oxidation, we must still inquire how we recognize the process of oxidation? We have seen how important a part combustion plays in the history of chemical speculation; and we may usefully form such classes of bodies as combustibles and supporters of combustion.

But even combustion is not capable of being infallibly known, for it passes by insensible shades into oxidation. We can find no basis for our reasonings, which does not assume a classification of obvious facts and

qualities.

But any classification of substances on such grounds, appears, at first sight, to involve us in vagueness, ambiguity, and contradiction. Do we really take the sensible qualities of an acid as the criterion of its being an acid?-for instance, its sourcess? Prussic acid, arsenious acid, are not sour. 'I remember,' says Dr. Paris, 'a chemist having been exposed to much ridicule from speaking of a succet acid,-why not?' When Davy had discovered potassium, it was disputed whether it was a metal, for though its lustre and texture are metallic, it is so light as to swim on water. And if potassium be allowed to be a metal, is silicium one, a body which wants the metallic lustre, and is a non conductor of electricity? It is clear that, at least, the obvious application of a classification by physical characters, is attended with endless perplexity.

But since we cannot even begin our researches without assuming a classification, and since the forms of such a classification which first occur, end in apparent confusion, it is clear that we must look to our philosophy for a solution of this difficulty; and must avoid the embarrassments and contradictions of casual and unreflective classification, by obtaining a consistent and philosophical arrangement. We must employ external characters and analogies in a connected and systematic manner; we must have Classificatory Sciences, and these must have a bearing even on

Chemistry.

Accordingly, the most philosophical chemists now proceed upon this principle. 'The method which I have followed,' says M. Thenard, in his Traité de Chimie, published in 1824, '18, to unite in one group all analogous bodies; and the advantage of this method,

¹ Life of Davy, 1, 263

which is that employed by naturalists, is very great, especially in the study of the metals and their compounds.'s In this, as in all good systems of chemistry, which have appeared since the establishment of the phlogistic theory, combustion, and the analogous processes, are one great element in the arrangement, while the difference of metallic and non-metallic, is another element. Thus Thenard, in the first place, speaks of Oxygen; in the next place, of the Nonmetallic Combustibles, as Hydrogen, Carbon, Sulphur, Chlorine; and in the next place, of Metals. But the Metals are again divided into six Sections, with reference, principally, to their facility of combination with oxygen. Thus, the First Section is the Metals of the Earths; the Second, the Metals of the Alkalies; the Third, the Easily Oxidable Metals, as Iron; the Fourth, Metals Less Oxidable, as Copper and Lead; the Fifth Section contains only Mercury and Osmium; and the Sixth, what were at an earlier period termed the Noble Metals, Gold, Silver, Platinum, and others.

How such principles are to be applied, so as to produce a definite and consistent arrangement, will be explained in apeaking of the philosophy of the Classificatory Sciences; but there are one or two peculiarities in the classes of bodies thus recognized by modern

chemistry, which it may be useful to notice.

1. The distinction of Metallic and Non-metallic is still employed, as of fundamental importance. The discovery of new metals is so much connected with the inquiries concerning chemical elements, that we may notice the general progress of such discoveries. Gold, Silver, Iron, Copper, Quickeilver, Lead, Tin, were known from the earliest antiquity. In the beginning of the sixteenth century, mine-directors, like George Agricola, had advanced so far in practical metallurgy, that they had discovered the means of extracting three additional metals, Zinc, Bismuth, Antimony. After this, there was no new metal discovered for a century, and then such discoveries were made by the theoretical

Pref., p. viii.

chemists, a race of men who had not existed before Beccher and Stahl. Thus Arsenic and Cobalt were made known by Brandt, in the middle of the eighteenth century, and we have a long list of similar discoveries belonging to the same period; Nickel, Manganese, and Tungsten, which were detected by Cronstedt, Gahn and Scheele, and Delhuyart, respectively; metals of a very different kind, Tellurium and Molybdenum, which were brought to light by Muller, Scheele, Bergman, and Hielm, Platinum, which was known as early as 1741, but with the ore of which, in 1802 and 1803, the English chemists, Wollaston and Tennant, found that no less than four other new metals (Palladium, Rhodium, Iridium, and Osmeum) were associated. Finally, (omitting some other new metals.) we have another period of discovery, opened in 1807, by Davy's discovery of Potassium, and including the resolution of all, or almost all, the alkalies and earths into metallic bases.

[2nd Ed,] [The next few years made some, at least some conjectural, additions to the list of simple substances, detected by a more minute scrutiny of known substances. Thorium was discovered by Berzehns in 1828, and Vanadium by Professor Sefstrom in 1830. A metal named Cerium, was discovered in 1803, by Hisinger and Berzelius, in a rare Swedish mineral known by the name of Cerit. Mosander more recently has found combined with Cerium, other new metals, which he has called Lanthanium, Dudymium, Erbum, and Terbium: M. Klaus has found a new metal, Ruthenium, in the ore of Platinum; and Rose has discovered in Tantalite two other new metals, which he has announced under the names of Pelopium and Niobium. Svanberg is said to have discovered a new earth in Eudialyt, which is supposed to have, like the rest, a new radical. If these last discoveries be confirmed, the number of simple substances will be raised to sixty-two.

2. Attempts have been made to indicate the classification of chemical substances by some peculiarity in the Name; and the Metals, for example, have been

designated generally by names in um, like the Latin names of the ancient metals, aurum, ferrum. This artifice is a convenient nomenclature for the purpose of marking a recognized difference, and it would be worth the while of chemists to agree to make it universal, by writing molybdenum and platinum; which is some-

times done, but not always.

3. I am not now to attempt to determine how far this class, -Metals, -extends, but where the analogies of the class cease to hold, there the nomenclature must also change. Thus, some chemists, as Dr. Thomson, have conceived that the base of Silica is more analogous to Carbon and Boron, which form acids with oxygen, than it is to the metals, and he has accordingly associated this base with these substances, and has given it the same termination, Silicon. But on the validity of this analogy chemists appear not to be

generally agreed.

4. There is another class of bodies which have attracted much notice among modern chemists, and which have also been assumilated to each other in the form of their names; the Eughsh writers calling them Chlorine, Fluorine, lodine, Bromine, while the French use the terms Chlore, Phtore, Iode, Brome. We have already noticed the establishment of the doctrine—that muriatic acid is formed of a base, chlorine, and of hydrogen, as a great reform in the oxygen theory, with regard to which rival claims were advanced by Davy, and by MM Gay-Lussac and Thenard in 1809. Iodine, a remarkable body which, from a dark powder, is converted into a violet-coloured gas by the application of heat, was also, in 1813, the subject of a similar rivalry between the same English and French chemists. Bromine was only discovered as late as 1826; and Fluorine, or Phtore, as, from its destructive nature, it has been proposed to term it, has not been obtained as a separate substance, and is inferred to exist by analogy only. The analogies of these bodies (Chlore, Phtore, &c.) are very peculiar; for instance, by combination with metals they form salts; by combination with hydrogen they form very strong acids; and all, at the common temperature of the atmosphere, operate on other bodies in the most energetic manner. Berzelius³ proposes to call them *halogenous* bodies, or

halogenes.

5. The number of Elementary Substances which are at present presented in our treatises of chemistry is fifty-three, or rather, as we have said above, sixtytwo.] It is naturally often asked what evidence we have, that all these are elementary, and what evidence that they are all the elementary bodies; -how we know that new elements may not hereafter be discovered, or these supposed simple bodies resolved into simpler still? To these questions we can only answer, by referring to the history of chemistry;by pointing out what chemists have understood by analysis, according to the preceding narrative. They have considered, as the analysis of a substance, that elementary constitution of it which gives the only intelligible explanation of the results of chemical manipulation, and which is proved to be complete as to quantity, by the balance, since the whole can only be equal to all its parts. It is impossible to maintain that new substances may not hereafter be discovered; for they may lurk, even in familiar substances, in doses so minute that they have not yet been missed amid the inevitable slight inaccuracies of all analysis; in the way in which iodine and bromine remained so long undetected in sea-water; and new minerals, or old ones not yet sufficiently examined, can hardly fail to add something to our list. As to the possibility of a further analysis of our supposed simple bodies, we may venture to say that, in regard to such supposed simple bodies as compose a numerous and well characterized class, no such step can be made, except through some great change in chemical theory, which gives us a new view of all the general relations which chemistry has yet discovered. The proper evidence of the reality of any supposed new analysis is, that it is more consistent with the known analogies of chemistry, to suppose the

² Chem. i. 464.

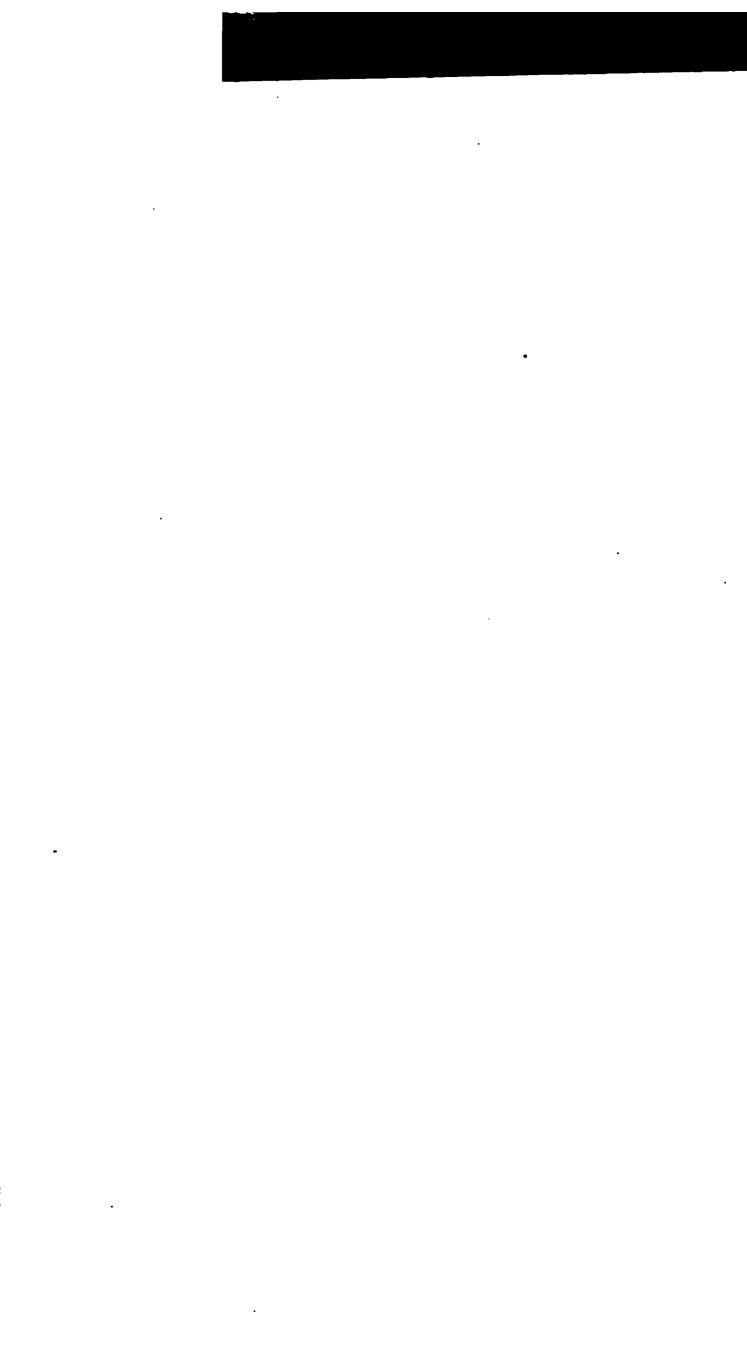

⁴ Turner, p. 971.

TRANSITION TO CLASSIFICATORY SCIENCE. 159

process analytical than synthetical. Thus, as has already been said, chemists admit the existence of fluorine, from the analogy of chlorine; and Davy, when it was found that ammonia formed an amalgam with mercury, was tempted to assign to it a metallic basis. But then he again hesitates, and doubts whether the analogies of our knowledge are not better preserved by supposing that ammonia, as a compound of hydrogen and another principle, is 'a type of the composition of the metals.'

Our history, which is the history of what we know, has little to do with such conjectures. There are, however, some not unimportant principles which bear upon them, and which, as they are usually employed, belong to the science which next comes under our review, Mineralogy.

Now, if the bold but pious thought be thine,
To reach our spacious temple's inner shrine,
Take in thy reverent bands the crystal stone,
Where heavenly light in earthy shroud is shown:
Where, moulded into measured form, with rays
Complex yet clear, the eternal Ether plays;
This if thou firmly hold and rightly use,
Not long the gods thy ardent wish refuse.

INTRODUCTION.

Sect. 1 .- Of the Classificatory Sciences.

THE horizon of the sciences spreads wider and wider before us, as we advance in our task of taking a survey of the vast domain. We have seen that the existence of Chemistry as a science which declares the ingredients and essential constitution of all kinds of bodies, implies the existence of another corresponding science, which shall divide bodies into kinds, and point out steadily and precisely what bodies they are which we have analysed. But a science thus dividing and defining bodies, is but one member of an order of sciences, different from those which we have hitherto described, namely, of the classificatory sciences. Such sciences there must be, not only having reference to the bodies with which chemistry deals, but also to all things respecting which we aspire to obtain any general knowledge, as, for instance, plants and animals. Indeed it will be found, that it is with regard to these latter objects, to organized beings, that the process of scientific classification has been most successfully exercised; while with regard to morganic substances, the formation of a satisfactory system of arrangement has been found extremely difficult; nor has the necessity of such a system been recognized by chemists so distinctly and constantly as it ought to be. The best exemplifications of these branches of knowledge, of which we now have to speak, will, therefore, be found in the organic world, in Botany and Zoology, but we will, in the first place, take a brief view of the science which classifies inorganic bodies, and of which Mineralogy is hitherto the very imperfect representative.

The principles and rules of the Classificatory Sciences, as well as of those of the other orders of sciences, must be fully explained when we come to treat of the Philosophy of the Sciences; and cannot be introduced here, where we have to do with history only. But I may observe very briefly, that with the process of classing, is joined the process of naming;that names imply classification, -and that even the rudest and earliest application of language presupposes a distribution of objects according to their kinds;but that such a spontaneous and unsystematic distribution cannot, in the cases we now have to consider, answer the purposes of exact and general knowledge. Our classification of objects must be made consistent and systematic, in order to be scientific; we must discover marks and characters, properties and conditions, which are constant in their occurrence and relations; we must form our classes, we must impose our names, according to such marks. We can thus, and thus alone, arrive at that precise, certain, and systematic knowledge, which we seek; that is, at science. The object, then, of the classificatory sciences is to obtain FIXED CHARACTERS of the kinds of things; and the criterion of the fitness of names is, that THEY MAKE GENERAL PROPOSITIONS POSSIBLE.

I proceed to review the progress of certain sciences on these principles, and first, though briefly, the science of Mineralogy.

Sect. 2.—Of Mineralogy as the Analytico-classificatory Science.

Mineralogy, as it has hitherto been cultivated, is, as I have already said, an imperfect representative of the department of human knowledge to which it belongs. The attempts at the science have generally been made by collecting various kinds of information respecting mineral bodies; but the science which we require is a complete and consistent classified system of all inorganic bodies. For chemistry proceeds upon the principle that the constitution of a body invariably determines its properties; and, consequently, its kind; but we cannot apply this principle, except we can speak with precision of the kind of a body, as well as

165

of its composition. We cannot attach any sense to the assertion, that 'soda or baryta has a metal for its base,' except we know what a metal is, or at least what properties it implies. It may not be, indeed it is not, possible, to define the kinds of bodies by words only; but the classification must proceed by some constant and generally applicable process, and the knowledge which has reference to the classification will be precise as far as this process is precise, and vague as far as

this is vague.

There must be, then, as a necessary supplement to Chemistry, a Science of those properties of bodies by which we divide them into kinds Mineralogy is the branch of knowledge which has discharged the office of such a science, so far as it has been discharged, and, indeed, Mineralogy has been gradually approaching to a clear consciousness of her real place, and of her whole task: I shall give the history of some of the advances which have thus been made. They are, principally, the establishment and use of External Characters, especially of Crystalline Form, as a fixed character of definite substances; and the attempts to bring into view the connexion of Chemical Constitution and External Properties, made in the shape of mineralogical Systems; both those in which chemical methods of arrangement are allopted, and those which profess to classify by the natural-history method.

CRYSTALLOGRAPHY.

CHAPTER I.

PRELUDE TO THE EPOCH OF DE LISLE AND HAÜY.

OF all the physical properties of bodies, there is none so fixed, and in every way so remarkable, as this:—that the same chemical compound always assumes, with the utmost precision, the same geometrical form. This identity, however, is not immediately obvious; it is often obscured by various mixtures and imperfections in the substance; and even when it is complete, it is not immediately recognized by a common eye, since it consists, not in the equality of the sides or faces of the figures, but in the equality of their angles. Hence it is not surprising that the constancy of form was not detected by the early observers. Pliny says,1 'Why crystal is generated in a hexagonal form, it is difficult to assign a reason; and the more so, since, while its faces are smoother than any art could make them, the pyramidal points are not all of the same kind.' The quarts crystals of the Alps, to which he refers, are, in some specimens, very regular, while in others, one side of the pyramid becomes much the largest; yet the angles remain constantly the same. But when the whole shape varied so much, the angles also seemed to vary. Thus Conrad Gessner, a very learned naturalist, who, in 1564, published at Zurich his work, De rerum Fossilium, Lapidum et Gemmarum maxime, Figuris, says,2 One crystal differs from another in its angles, and consequently in its figure.' And Cæsalpinus, who, as we shall find, did so much in establishing fixed characters in botany, was led by some of his general views to

¹ Not. Hist, xxvii, 3.

disbelieve the fixity of the form of crystals. In his work De Metallicis, published at Nuremberg in 1602, he says,3 'To ascribe to inanimate bodies a definite form, does not appear consentaneous to reason; for it is the office of organization to produce a definite form; an opinion very natural in one who had been immersed in the study of the general analogies of the forms of plants. But though this is excusable in Casalpinus. the rejection of this definiteness of form a hundred and eighty years later, when its existence had been proved, and its laws developed by numerous observers, cannot be ascribed to anything but strong prejudice; yet this was the course taken by no less a person than Buffon, 'The form of crystallization, says he, 'is not a constant character, but is more equivocal and more variable than any other of the characters by which minerals are to be distinguished.' And accordingly, he makes no use of this most important feature in his history of minerals. This strange perverseness may perhaps be ascrabed to the dislike which Buffon is said to have entertained for Linnaeus, who had made crystalline form a leading character of minerals.

It is not necessary to mark all the minute steps by which mineralogists were gradually led to see clearly the nature and laws of the fixity of crystalline forms. These forms were at first noticed in that substance which is peculiarly called rock-crystal or quartz; and afterwards in various stones and gems, in salts obtained from various solutions, and in snow. But those who observed the remarkable regular figures which these substances assume, were at first impelled onwards in their speculations by the natural tendency of the human mind to generalize and guess, rather than to examine and measure. They attempted to snatch at once the general laws of geometrical regularity of these occurrences, or to connect them with some doctrine concerning formative causes. Thus Kepler,5 in his Harmonics of the World, asserts a 'formatrix facultas, which has its seat in the entrails of the earth, and,

¹ p. 97.

⁴ Hiet, des Min. p. 343. Linz. 1619, p. 161,

after the manner of a pregnant woman, expresses the five regular geometrical solids in the forms of gems." But philosophers, in the course of time, came to build more upon observation, and less upon abstract reason-Nicolas Steno, a Dane, published, in 1669, a dissertation De Solido intra Solidum Naturaliter contento, in which he says,6 that though the sides of the hexagonal crystal may vary, the angles are not changed. And Dominic Gulielmini, in a Dissertation on Salts, published in 1707, says,7 in a true inductive spirit, Nature does not employ all figures, but only certain ones of those which are possible; and of these, the determination is not to be fetched from the brain, or proved a priori, but obtained by experiments and observations.' And he speaks with entire decision on this subject: 'Nevertheless since there is here a principle of crystallization, the inclination of the planes and of the angles is always constant.' He even anticipates, very nearly, the views of later crystallographers as to the mode in which crystals are formed from elementary molecules. From this time, many persons laboured and speculated on this subject; as Cappeller, whose Prodromus Crystallographic appeared at Lucera in 1723; Bourgnet, who published Lettres Philosophiques sur la Formation de Sels et de Cristaux, at Amsterdam, in 1792; and Henckel, the 'Physicus' of the Elector of Saxony, whose Pyritologia came forth in 1725. In this last work we have an example of the description of the various forms of special classes of minerals, (iron pyrites, copper pyrites, and arsenic pyrites;) and an example of the enthusiasm which this apparently dry and laborious study can excite 'Neither tongue nor stone,' he exclaims, 'can express the satisfaction which I received on setting eyes upon this sinter covered with galena; and thus it constantly happens, that one must have more pleasure in what seems worthless rubbish, than in the purest and most precious ores, if we know aught of minerals."

6 p. 69. 7 p. 19. 6 p. 93. 5 p. 343.

Still, however, Henckel 10 disclaims the intention of

arranging minerals according to their mathematical forms; and this, which may be considered as the first decided step in the formation of crystallographic mineralogy, appears to have been first attempted by Linneus. In this attempt, however, he was by no means happy; nor does he himself appear to have been satisfied. He begins his preface by saying, 'Lithology is not what I plume myself upon.' (Lithologia mihi cristas non eriget.) Though his sagacity, as a natural historian, led him to see that crystalline form was one of the most definite, and therefore most important, characters of minerals, he failed in profiting by this thought, because, in applying it, he did not employ the light of geometry, but was regulated by what appeared to him resemblances, arbitrarily selected, and often delusive. 11 Thus he derived the form of pyrites from that of vitriol,12 and brought together alum and damond on account of their common octohedral form. But he had the great merit of animating to this study one to whom, more perhaps than to any other person, it owes its subsequent progress; I mean Romé de Lisle. 'Instructed,' this writer says, in his preface to his Essais de Crystallographie, 'by the works of the celebrated Von Linnée, how greatly the study of the angular form of crystals might become interesting, and fitted to extend the sphere of our mineralogical knowledge. I have followed them in all their metamorphoses with the most scrupulous attention.' The views of Linnaus, as to the importance of this character, had indeed been adopted by several others, as John Hill, the King's gardener at Kew, who, in 1777, published his Spathogenena, and Grignon, who, in 1775, says, These crystallizations may give the means of finding a new theory of the generation of crystalline gema.'

The circumstance which threw so much difficulty in the way of those who tried to follow out this thought was, that in consequence of the apparent irregularity of crystals, arising from the extension or contraction of particular sides of the figure, each kind of substance

¹¹ Mark, Gesch. p. 97

may really appear under many different forms, connected with each other by certain geometrical relations. These may be conceived by considering a certain fundamental form to be cut into new forms in particular ways. Thus if we take a cube, and cut off all the eight corners, till the original faces disappear, we make it an octohedron; and if we stop short of this, we have a figure of fourteen faces, which has been called a cubooctohedron. The first person who appears distinctly to have conceived this truncation of angles and edges, and to have introduced the word, is Démeste;13 although Wallerius 14 had already said, in speaking of the various crystalline forms of calcapar, 'I conceive it would be better not to attend to all differences, lest we be overwhelmed by the number.' And Werner, in his celebrated work On the External Characters of Minerals, 15 had formally spoken of truncation, acuation, and acumination, or replacement by a plane, an edge, a point, respectively, (abstumpfung, zuschärfung, zuspitzung,) as ways in which the forms of crystals are modified and often disguised. He applied this process in particular to show the connexion of the various forms which are related to the cube. But still the extension of the process to the whole range of minerals and other crystalline bodies, was due to Romé de Lisle.

CHAPTER IL

EPOCH OF ROME DE LISLE AND HAUY.—ESTABLISH-MENT OF THE FIXITY OF CRYSTALLINE ANGLES, AND THE SIMPLICITY OF THE LAWS OF DERIVATION.

L have already seen that, before 1780, several mineralogists had recognized the constancy of the angles of crystals, and had seen (as Démeste and Werner,) that the forms were subject to modifications of a definite kind. But neither of these two thoughts was so apprehended and so developed, as to supersede the occasion for a discoverer who should put forward these principles as what they really were, the materials of a new and complete science. The merit of this step belongs jointly to Romé de Lisle and to Hany. The former of these two men had already, in 1772, published an Essai de Crystallographie, in which he had described a number of crystals. But in this work his views are still rude and vague; he does not establish any connected sequence of transitious in each kind of substance, and lays little or no stress on the angles. But in 1783, his ideas had reached a maturity which, by comparison, excites our admiration In this he asserts, in the most distinct manner, the invariability of the angles of crystals of each kind, under all the changes of relative dimension which the faces may undergo,2 and he points out that this invariability applies only to the primitive forms, from each of which many secondary forms are derived by various changes.3 Thus we cannot deny him the merit of having taken steady hold on both the handles of this discovery, though something still remained for another to do. Romé pursues his general ideas into detail with great labour and skill. He gives drawings of more than five hundred regular forms; (in his first work he had

p. 68.

¹ Cristallographie, ou Description de Formes propres à tous les Corps du Règne Minéral. 3 vols. and 1 vol of plates.

inserted only one hundred and ten; Linnæus only knew forty;) and assigns them to their proper substances; for instance, thirty to calcapar, and sixteen to felspar. He also invented and used a goniometer. We cannot doubt that he would have been looked upon as a great discoverer, if his fame had not been dimmed by the more brilliant success of his contemporary

Haüy.

Réné-Just Hauy is rightly looked upon as the founder of the modern school of crystallography; for all those who have, since him, pursued the study with success, have taken his views for their basis. Besides publishing a system of crystallography and of mineralogy, far more complete than any which had yet appeared, the peculiar steps in the advance which belong to him are, the discovery of the importance of cleavage, and the consequent expression of the laws of derivation of secondary from primary forms, by means of the decrements of the successive layers of integrant molecules.

The latter of these discoveries had already been, in some measure, anticipated by Bergman, who had, in 1773, conceived a hexagonal prism to be built up by the juxta-position of solid rhombs on the planes of a rhombic nucleus.4 It is not clear whether Hauy was acquainted with Bergman's Memoir, at the time when the cleavage of a hexagonal prism of calcapar, accidentally obtained, led him to the same conception of its structure. But however this might be, he had the indisputable credit of following out this conception with all the vigour of originality, and with the most laborious and persevering earnestness; indeed he made it the business of his life. The hypothesis of a solid, built up of small solids, had this peculiar advantage in reference to crystallography; it rendered a reason of this curious fact, -that a certain series of forms occur in crystals of the same kind, while other forms, apparently intermediate between those which actually

⁴ De Pormis Crystallorum. Nov. Act. Reg. Soc. Sc. Ups 1773.
5 Tradé de Muiér. 1822, i. 15.

occur, are rigorously excluded. The doctrine of decrements explained this; for by placing a number of regularly-decreasing rows of equal solids, as, for instance, of bricks, upon one another, we might form a regular equal-sided triangle, as the gable of a house; and if the breadth of the gable were one hundred bricks, the height of the triangle might be one hundred, or fifty, or twenty-five, but it would be found that if the height were an intermediate number, as fifty-seven, or forty-three, the edge of the wall would become irregular; and such irregularity is assumed to be inadiussible in the regular structure of crystals. Thus this mode of conceiving crystals allows of certain definite secon-

dary forms, and no others,

The mathematical deduction of the dimensions and proportions of these secondary forms, -the invention of a notation to express them; -the examination of the whole mineral kingdom in accordance with these views .- the production of a works in which they are explained with singular clearness and vivacity; -are services by which Hauy richly earned the admiration which has been bestowed upon him. The wonderful copiousness and variety of the forms and laws to which he was led, thoroughly exercised and nourished the spirit of deduction and calculation which his discoveries excited in him. The reader may form some conception of the extent of his labours, by being told—that the mere geometrical propositions which he found it necessary to premise to his special descriptions, occupy a volume and a half of his work; -that his diagrams are nearly a thousand in number; -that in one single substance (calespar) he has described forty-seven varieties of form, - and that he has described one kind of crystal (called by him fer sulfuré parallélique) which has one hundred and thirty-four faces.

In the course of a long life, he examined, with considerable care, all the forms he could procure of all kinds of mineral; and the interpretation which he gave of the laws of those forms was, in many cases, fixed, by

⁶ Traité de Minéralogie, 1801, 5 vois,

means of a name applied to the mineral in which the form occurred; thus, he introduced such names as equiaxe, métastutique, unibinaire, perihexahèdre, bisalterne, and othera. It is not now desirable to apply separate names to the different forms of the same mineral species, but these terms answered the purpose, at the time, of making the subjects of study more definite. A symbolical notation is the more convenient mode of designating such forms, and such a notation Haüy invented; but the symbols devised by him had many inconveniences, and have since been superseded

by the systems of other crystallographers.

Another of Hauy's leading merits was, as we have already intimated, to have shown, more clearly than his predecessors had done, that the crystalline angles of substances are a criterion of the substances; and that this is peculiarly true of the angles of cleavage. that is, the angles of those edges which are obtained by cleaving a crystal in two different directions; a mode of division which the structure of many kinds of crystals allowed him to execute in the most complete manner. As an instance of the employment of this criterion, I may mention his separation of the sulphates of haryta and of strontia, which had previously been confounded. Among crystals which in the collections were ranked together as 'heavy spar,' and which were so perfect as to admit of accurate measurement, he found that those which were brought from Sicily, and those of Derbyshire, differed in their cleavage angle by three degrees and a half. 'I could not suppose,' he says,7 that this difference was the effect of any law of decrement; for it would have been necessary to suppose so rapid and complex a law, that such an hypothesis might have been justly regarded as an abuse of the theory.' He was, therefore, in great perplexity. But a little while previous to this, Klaproth had discovered that there is an earth which, though in many respects it resembles baryta, is different from it in other respects; and this earth, from the place where it was found (in

⁷ Traité, ii. 340.

Scotland), had been named Strontia. The French chemists had ascertained that the two earths had, in some cases, been mixed or confounded; and Vauquelin, on examining the Sicilian crystals, found that their base was strontia, and not, as in the Derbyshire ones, baryta. The riddle was now read; all the crystals with the larger angle belong to the one, all those with the smaller, to the other, of these two sulphates; and crystallometry was clearly recognized as an authorized test of the difference of substances which nearly resemble each other

Enough has been said, probably, to enable the reader to judge how much each of the two persons, now under review, contributed to crystallography. It would be unwise to compare such contributions to science with the great discoveries of astronomy and chemistry; and we have seen how nearly the predecessors of Romé and Hauy had reached the point of knowledge on which these two crystallographers took their stand. But yet it is impossible not to allow, that in these discoveries, which thus gave form and substance to the science of crystallography, we have a manifestation of no common sagnerty and skill. Here, as in other discoveries, were required ideas and facts;—clearness of geometrical concention which could deal with the most complex relations of form; a minute and extensive acquaintance with actual crystals; and the talent and habit of referring these facts to the general ideas. Hauy, in particular, was happily endowed for his task. Without being a great mathematician, he was sufficiently a geometer to solve all the problems which his undertaking demanded; and though the mathematical reasoning might have been made more compendious by one who was more at home in mathematical generalization, probably this could hardly have been done without making the subject less accessible and less attractive to persons moderately disciplined in mathematics. In all his reasonings upon particular cases, Hauy is seute and clear; while his general views appear to be suggested rather by a lively fancy than by a sage inductive spirit: and though he thus misses the character of a great philosopher, the vivacity of style, and felicity and happiness of illustration, which grace his book, and which agree well with the character of an Abbé of the old French monarchy, had a great and useful influence on the progress of the

subject.

Unfortunately Romé de Lisle and Hauy were not only rivals, but in some measure enemies. The former might naturally feel some vexation at finding himself. in his later years (he died in 1790), thrown into shade by his more brilliant successor. In reference to Hauy's use of cleavage, he speaks of 'muovators in crystallography, who may properly be called crystalloclasts. Yet he adopted, in great measure, the same views of the formation of crystals by laminæ, which Hauy illustrated by the destructive process at which he thus sneers. His sensitiveness was kept alive by the conduct of the Academy of Sciences, which took no notice of him and his labours; 10 probably because it was led by Buffon, who disliked Linnaus, and might dislike Romé as his followe.; and who, as we have seen, despised crystallography. Hauy revenged himself by rarely mentioning Romé in his works, though it was manifest that his obligations to him were immense; and by recording his errours while he corrected them. More fortunate than his rival, Hauy was, from the first, received with favour and applause. His lectures at Paris were eagerly listened to by persons from all quarters of the world. His views were, in this manner, speedily diffused; and the subject was soon pursued. in various ways, by mathematicians and mineralogists in every country of Europe.

Pref., p. xxvii. T. ii. p. 21.

CHAPTER III.

RECEPTION AND CORRECTIONS OF THE HAUTAN
CRYSTALLOGRAPHY.

I HAVE not hitherto noticed the imperfections of the crystallographic views and methods of Hady, because my business in the last section was to mark the permanent additions he made to the science. His system did, however, require completion and rectification in various points; and in speaking of the crystallographers of the subsequent time, who may all be considered as the cultivators of the Hadian doctrines, we must also consider what they did in correcting them.

The three main points in which this improvement was needed were;—a better determination of the cryatalline forms of the special substances;—a more general and less arbitrary method of considering cryatalline forms according to their symmetry;—and a detection of more general conditions by which the crystalline angle is regulated. The first of these processes may be considered as the natural sequel of the Haman epoch: the other two must be treated as

separate steps of discovery.

When it appeared that the angle of natural or of cleavage faces could be used to determine the differences of minerals, it became important to measure this angle with accuracy. Hauy's measurements were found very inaccurate by many succeeding crystallographers; Mohs says! that they are so generally inaccurate, that no confidence can be placed in them. This was said, of course, according to the more rigorous notions of accuracy to which the establishment of Hany's system led. Among the persons who principally laboured in ascertaining, with precision, the crystalline angles of minerals, were several Englishmen, especially Wolfaston, Phillips, and Brooke. Wolfaston, by the invention of

Marx. p. 153.

his Reflecting Goniometer, placed an entirely new degree of accuracy within the reach of the crystallographer; the angle of two faces being, in this instrument, measured by means of the reflected images of bright objects seen in them, so that the measure is the more accurate the more minute the faces are. In the use of this instrument, no one was more laborious and successful than William Phillips, whose power of apprehending the most complex forms with steadiness and clearness, led Wollaston to say that he had a geometrical sense. Phillips published a Treatise on Mineralogy, containing a great collection of such determinations; and Mr Brooke, a crystallographer of the same exact and careful school, has also published several works of the same kind. The precise measurement of crystalline angles must be the familiar employment of all who study crystallography; and, therefore, any further enumeration of those who have added, in this way, to the stock of knowledge, would be superfluous.

Nor need I dwell long on those who added to the knowledge which Haiiy left, of derived forms. The most remarkable work of this kind was that of Count Bournon, who published a work on a single mineral (calcspar) in three quarto volumes. He has here given representations of seven hundred forms of crystals, of which, however, only fifty-six are essentially different. From this example the reader may judge what a length of time, and what a number of observers and calculators.

were requisite to exhaust the subject.

If the calculations, thus occasioned, had been conducted upon the basis of Hauy's system, without any further generalization, they would have belonged to that process, the natural sequel of inductive discoveries, which we call deduction; and would have needed only a very brief notice here. But some additional steps were made in the upward road to scientific truth, and of these we must now give an account.

^{*} Traité complet de la Chaux Carbonatée et d'Aragonite, par M le Comte de Bournon. London, 1808.

CHAPTER IV.

ESTABLISHMENT OF THE DISTINCTION OF SYSTEMS OF CRYSTALLIZATION.—WEISS AND MORS.

In Haily's views, as generally happens in new systems, however true, there was involved something that was arbitrary, something that was false or doubtful, something that was unnecessarily limited. The principal points of this kind were;—his having made the laws of crystalline derivation depend so much upon cleavage,—his having assumed an atomic constitution of bodies as an essential part of his system;—and his having taken a set of primary forms, which, being selected by no general view, were partly superfluous,

and partly defective.

How far evidence, such as has been referred to by various philosophers, has proved, or can prove, that bodies are constituted of indivisible atoms, will be more fully examined in the work which treats of the Philosophy of this subject. There can be little doubt that the portion of Hauy's doctrine which most riveted popular attention and applause, was his dissection of crystals, in a manner which was supposed to lead actually to their ultimate material elements. Yet it is clear, that since the solids given by cleavage are, in many cases, such as cannot make up a solid space, the primary conception, of a necessary geometrical identity between the results of division and the elements of composition, which is the sole foundation of the supposition that crystallography points out the actual elements, disappears on being scrutinized: and when Hauy, pressed by this difficulty, as in the case of fluorspar, put his integrant octohedral molecules together, touching by the edges only, his method became an empty geometrical diagram, with no physical meaning

The real fact, divested of the hypothesis which was contained in the fiction of decrements, was, that when the relation of the derivative to the primary faces is expressed by means of numerical indices, these numbers are integers, and generally very small ones; and this was the form which the law gradually assumed, as the method of derivation was made more general and

simple by Weiss and others.

When, in 1809, I published my Dissertation, says Weiss,1 'I shared the common opinion as to the necessity of the assumption and the reality of the existence of a primitive form, at least in a sense not very different from the usual sense of the expression. While I sought,' he adds, referring to certain doctrines of general philosophy which he and others entertained, 'a dynamical ground for this, instead of the untenable atomistic view, I found that, out of my primitive forms, there was gradually unfolded to my hands, that which really governs them, and is not affected by their casual fluctuations, the fundamental relations of those Dimensions according to which a multiplicity of internal oppositions, necessarily and mutually interdependent, are developed in the mass, each having its own polarity, so that the crystalline character is coextensive with these polarities.'

The 'Dimensions' of which Weiss here speaks, are the Axes of Symmetry of the crystal, that is, those lines, in reference to which, every face is accompanied by other faces, having like positions and properties. Thus a rhomb, or more properly a rhombohedron, of calc-spar may be placed with one of its obtuse corners uppermost, so that all the three faces which meet there are equally inclined to the vertical line. In this position, every derivative face, which is obtained by any modification of the faces or edges of the rhombohedron. implies either three or six such derivative faces; for no one of the three upper faces of the rhombohedron has any character or property different from the other two; and, therefore, there is no reason for the existence of a derivative from one of these primitive faces, which does not equally hold for the other primitive

¹ Mem Acad Berl 18:6, p. 307.

I use this name for the solid figure, since rhomb has always been need for a plane figure.

faces. Hence the derivative forms will, in all cases, contain none but faces connected by this kind of correspondence. The axis thus made vertical will be an Axis of Symmetry, and the crystal will consist of three divisions, ranged round this axis, and exactly resembling each other. According to Weiss's nomenclature, such a crystal is 'three-and-three-membered.'

But this is only one of the kinds of symmetry which crystaline forms may exhibit. They may have three ares of complete and equal symmetry at right angles to each other, as the cube and the regular octohedron;—or, two axes of equal symmetry, perpendicular to each other and to a third axis, which is not affected with the same symmetry with which they are, such a figure is a square pyramid,—or they may have three rectangular axes, all of unequal symmetry, the modifications referring to each axis separately from the other two.

These are essential and necessary distinctions of crystalline form; and the introduction of a classification of forms founded on such relations, or as they were called, Systems of Crystallization, was a great improvement upon the divisions of the earlier crystallographers, for those divisions were separated according to certain arbitrarily-assumed primary forms. Thus Romé de Lisle's faudamental forms were, the tetrahedron, the cube, the octohedron, the rhombic prism, the rhombic octohedron, the dodecahedron with triangular faces: Hady's primary forms are the cube, the rhombohedron, the oblique rhombic prism, the right rhombic prism, the rhombic dodecahedron, the regular octohedron, tetrahedron, and six sided prism, and the bipyramidal dedecahedron. This division, as I have already said, errs both by excess and defect, for some of these primary forms might be made derivatives from others; and no solid reason could be assigned why they were not. Thus the cube may be derived from the tetrahedron, by truncating the edges; and the rhombic dodecahedron again from the cube, by truncating its edges; while the square pyramid could not be legitimately identified with the derivative of any of these forms; for if we were to derive it from the rhombic prism, why should the acute angles always suffer decrements corresponding in a certain way to those of the obtuse angles, as they must do in order to

give rise to a square pyramid?

The introduction of the method of reference to Systems of Crystallization has been a subject of controversy, some ascribing this valuable step to Weiss. and some to Mohs.3 It appears, I think, on the whole, that Weiss first published works in which the method is employed; but that Mohs, by applying it to all the known species of minerals, has had the merit of making it the basis of real crystallography. Weiss, in 1800. published a Dissertation On the mode of investigating the principal geometrical character of crystalline forms. in which he says, 'No part, line, or quantity, is so important as the axis; no consideration is more essential or of a higher order than the relation of a crystalline plane to the axis, and again, 'An axis is any line governing the figure, about which all parts are aimilarly disposed, and with reference to which they correspond mutually.' This he soon followed out by examination of some difficult cases, as Felspar and Epidote. In the Memoirs of the Berlin Academy. for 1814-5, he published An Exhibition of the natural Divisions of Systems of Crystallization. In this Memoir. his divisions are as follows -The regular system, the four-membered, the two-and-two-membered, the threeand-three-membered, and some others of inferior degrees of symmetry. These divisions are by Mohs (Outlines of Mineralogy, 1822,) termed the tessular, pyramidal, prismatic, and rhombohedral systems respectively. Hausmann, in his Investigations concerning the Forms of Inaumute Nature,6 makes a nearly corresponding arrangement :- the isometric, monodimetric, trimetric, and monotrimetric; and one or other of these sets of terms have been adopted by most succeeding writers.

In order to make the distinctions more apparent, I

² Edin Phil, Trans. 1823, vols. xv. and xvi. ⁴ pp. 16, 42. ⁵ Ibid. ⁶ Gottingen, 1821.

have purposely omitted to speak of the systems which arise when the prismatic system loses some part of its symmetry; when it has only half or a quarter its complete number of faces;—or, according to Moha's phraseology, when it is hemihedral or tetartohedral. Such systems are represented by the singly-oblique or doubly oblique prism; they are termed by Weiss two-and-one membered, and one-and-one-memberal; by other writers, Monoklinometric, and Triklinometric Systems. There are also other peculiarities of Symmetry, such, for instance, as that of the playibedral faces of quartz, and other minerals.

The introduction of an arrangement of crystalline forms into systems, according to their degree of symmetry, was a step which was rather founded on a distinct and comprehensive perception of mathematical relations, than on an acquaintance with experimental facts, beyond what earlier mineralogists had possessed. This arrangement was, however, remarkably confirmed by some of the properties of minerals which attracted notice about the time now spoken of, as we shall see

in the next chapter.

CHAPTER V.

RECEPTION AND CONFIRMATION OF THE DISTINCTION OF SYSTEMS OF CRYSTALLIZATION.

IFFUSION of the Distinction of Systems.—The distinction of systems of crystallization was so far founded on obviously true views, that it was speedily adopted by most mineralogists. I need not dwell on the steps by which this took place. Mr. Haidinger's translation of Mohs was a principal occasion of its introduction in England. As an indication of dates, bearing on this subject, perhaps I may be allowed to notice, that there appeared in the Philosophical Transactions for 1825, A General Method of Calculating the Angles of Crystals, which I had written, and in which I referred only to Hauy's views; but that in 1826, I published a Memoir On the Classification of Crystalline Combinations, founded on the methods of Weiss and Mohs, especially the latter; with which I had in the mean time become acquainted. and which appeared to me to contain their own evidence and recommendation. General methods, such as was attempted in the Memoir just quoted, are part of that process in the history of sciences, by which, when the principles are once established, the mathematical operation of deducing their consequences is made more and more general and symmetrical: which we have seen already exemplified in the history of celestial mechanics after the time of Newton. does not enter into our plan, to dwell upon the various steps in this way made by Levy, Naumann, Grassmann, Kupfler, Hessel, and by Professor Miller among ourselves. I may notice that one great improvement was, the method introduced by Monteiro and Levy, of determining the laws of derivation of forces by means of the parallelisms of edges; which was afterwards

¹ Camb. Truns. vol. ii p. 391.

extended so that faces were considered as belonging to zones. Nor need I attempt to enumerate (what indeed it would be difficult to describe in words) the various methods of notation by which it has been proposed to represent the faces of crystals, and to facilitate the calculations which have reference to them.

[2nd Ed] [My Memoir of 1825 depended on the views of Hauv in so far as that I started from his 'primitive forms; but, being a general method of expressing all forms by co-ordinates, it was very little governed by those views. The mode of representing crystalline forms which I proposed seemed to contain its own evidence of being more true to nature than Hauy's theory of decrements, inasmuch as my method expressed the faces by much lower numbers. I determine a face by means of the dimensions of the primary form divided by certain numbers; Hauy had expressed the face virtually by the same dimensions multiplied by numbers. In cases where my notation gives such numbers as (3. 4. 1), (1, 3. 7), (5, 1, 19), his method involves the higher numbers (4, 3, 12), (21, 7, 3), (19, 95. 5). My method however has, I believe, little value as a method of 'calculating the angles of crystals.'

M. Neumann, of Konigsberg, introduced a very convenient and elegant method of representing the position of faces of crystals by corresponding points on the surface of a circumscribing sphere. He gave (in 1823) the laws of the derivation of crystalline faces, expressed geometrically by the intersection of zones, (Bestrage zur Krystallonomie.) The same method of indicating the position of faces of crystals was afterwards, together with the notation, re invented by M. Grassmann, (Zur Krystallonomie und Geometrischen Combinationslehre, 1829) Aiding himself by the suggestions of these writers, and partly adopting my method, Prof. Miller has produced a work on Crystallography remarkable for mathematical elegance and symmetry; and has given expressions really useful for calculating the angles of crystalline faces, (A Treatise on Crystallography. Cambridge, 1830.)]

Confirmation of the Distinction of Systems by the Optical Properties of Minerals.—Brewster.—I must not omit to notice the striking confirmation which the distinction of systems of crystallization received from optical discoveries, especially those of Sir D. Brewster. Of the history of this very rich and beautiful department of science, we have already given some account, in speaking of Optics. The first facts which were noticed, those relating to double refraction, belonged exclusively to crystals of the rhombohedral system. The splendid phenomena of the rings and lemniscates produced by dipolarizing crystals, were afterwards discovered; and these were, in 1817, classified by Sir David Brewster, according to the crystalline forms to which they belong. This classification, on comparison with the distinction of Systems of Crystallization, resolved itself into a necessary relation of mathematical symmetry: all crystals of the pyramidal and rhombohedral systems, which from their geometrical character have a single axis of symmetry, are also optically uniaxal, and produce by dipolarization circular rings; while the prismatic system, which has no such single axis, but three unequal axes of symmetry, is optically biaxal, gives lemniscates by dipolarized light, and, according to Fresnel's theory, has three rectangular axes of unequal elasticity.

[2nd Ed.] [I have placed Sir David Brewster's arrangement of crystalline forms in this chapter, as an event belonging to the confirmation of the distinctions of forms introduced by Weiss and Mohs; because that arrangement was established, not on crystallographical, but on optical grounds. But Sir David Brewster's optical discovery was a much greater step in science than the systems of the two German crystallographers; and even in respect to the crystallographical principle, Sir D. Brewster had an independent share in the discovery. He divided crystalline forms into three classes, enumerating the Hauian primitive forms' which belonged to each; and as he found some exceptions to this classification, (such as idocrase, &c.,) he ventured to pronounce that in

those substances the received primitive forms were probably erroneous, a judgment which was soon confirmed by a closer crystallographical scrutiny. He also showed his perception of the mineralogical importance of his discovery by publishing it, not only in the Phil. Trans. (1818), but also in the Transactions of the Wernerian Society of Natural History. In a second paper inserted in this latter series, read in 1820, he further notices Mohs's System of Crystallography, which had then recently appeared, and points out its agreement with his own.

Another reason why I do not make this great optical discovery a cardinal point in the history of crystallography is, that as a crystallographical system it is incomplete. Although we are thus led to distinguish the tessular and the prismatic systems (using Mohs's terms) from the rhombohedral and the aquare prismatic, we are not led to distinguish the latter two from each other, masmuch as they have no optical difference of character. But this distinction is quite essential in crystallography; for these two systems have faces formed by laws as different as those of the other two systems.

Moreover, Weiss and Mohs not only divided crystalline forms into certain classes, but showed that by doing this, the derivation of all the existing forms from the fundamental ones assumed a new aspect of simplicity and generality; and this was the essential

part of what they did.

On the other hand, I do not think it is too much to say, as I have elsewhere said,² that 'Sir D. Brewster's optical experiments must have led to a classification of crystals into the above systems, or something nearly equivalent, even if crystals had not been so arranged by attention to their forms.'

Many other most curious trains of research have confirmed the general truth, that the degree and kind of geometrical symmetry corresponds exactly with the symmetry of the optical properties. As an instance

Philosophy of the Inductive Sciences, B. vili C. ili, Art. 3.

of this, eminently striking for its singularity, we may notice the discovery of Sir John Herschel, that the plagihedral crystallization of quartz, by which it exhibits faces twisted to the right or the left, is accompanied by right-handed or left-handed circular polarization respectively. No one acquainted with the subject can now doubt, that the correspondence of geometrical and optical symmetry is of the most complete and fundamental kind.

[2nd Ed.] [Our knowledge with respect to the positions of the optical axes of oblique prismatic crystals is still imperfect. It appears to be ascertained that, in singly oblique crystals, one of the axes of optical elasticity coincides with the rectangular crystallographic axis. In doubly-oblique crystals, one of the axes of optical elasticity is, in many cases, coincident with the axis of a principal zone. I believe no more

determinate laws have been discovered.]

Thus the highest generalizations at which mathematical crystallographers have yet arrived, may be considered as fully established, and the science of Crystallography, in the condition in which these place it, is fit to be employed as one of the members of Mineralogy, and thus to fill its appropriate place and office.

CHAPTER VI.

CORRECTION OF THE LAW OF THE SAME ANGLE FOR THE SAME SUBSTANCE.

ISCOVERY of Isomorphism. Mitscherlich, -The discovery of which we now have to speak may appear at first sight too large to be included in the history of crystallography, and may seem to belong rather to chemistry. But it is to be recollected that crystallography, from the time of its first assuming in portance in the hands of Hauy, founded its claim to notice entirely upon its connexion with chemistry; cry-talline forms were properties of something; but what that something was, and how it might be modified without becoming something else, no crystallographer could venture to decide, without the aid of chemical analysis. Hany had assumed, as the general result of his researches, that the same chemical elements, combined in the same proportions, would always exhibit the same crystailine form; and reciprocally, that the same form and angles (except in the obvious case of the tessular system, in which the angles are determined by its being the tessular system,) implied the same chemical constitution. But this dogma could only be considered as an approximate conjecture; for there were many glaring and unexplained exceptions to it. The explanation of several of these was beautifully described by the discovery that there are various elements which are isomorphous to each other; that is, such that one may take the place of another without altering the crystalline form; and thus the chemical composition may be much changed, while the crystallographic character is undisturbed.

This truth had been caught sight of, probably as a guess only, by Fuchs as early as 1815. In speaking of a mineral which had been called Gehlenite, he says,

again draws attention to rende.) which undoubtedly general law afterwards esta

But Fuchs's conjectural prelude to Mitscherlich's isomorphism. Till many o substance and signification vicarious elements, it was of one was more capable than best advantage any ideas w chemical world; yet we find upon a certain vague view of which contain equal doses of general properties common; definite conclusions. gave this proposition a real . Thus he found that the carb of magnesia, of protoxide of manganese, agree in many r homologous angles vary thre only, so again the carbonate and lime (arragonite), agree r of felspar vary only by the for another; the phosphates

isomorphous; or in the latter instance, that the arsenic and phosphoric acids are isomorphous.

Since, in some of these cases, the substitution of one element of the isomorphous group for another does alter the angle, though slightly, it has since been pro-

posed to call such groups pleacomorphous.

This discovery of isomorphism was of great importance, and excited much attention among the chemists of Europe. The history of its reception, however, belongs, in part, to the classification of minerals; for its effect was immediately to metamorphose the existing chemical systems of arrangement. But even those crystallographers and chemists who cared little for general systems of classification, received a powerful impulse by the expectation, which was now excited, of discovering definite laws connecting chemical constitution with crystalline form. Such investigations were soon carried on with great activity. Thus, at a recent period, Abich analysed a number of tessular minerals, spinelle, pleonaste, galnite, franklimite, and chromic iron oxide, and seems to have had some success in giving a common type to their chemical formulæ, as there is a common type in their crystal-

[2nd Ed.] [It will be seen by the above account that Prof. Mitscherlich's merit in the great discovery of Isomorphism is not at all narrowed by the previous conjectures of M. Fuchs. I am informed, moreover, that M. Fuchs afterwards (in Schweigger's Journal) retracted the opinions he had put forwards on this

subject.

connected truths which have been obtained by philosophers, rather than insulated difficulties which still stand out to perplex them. I need not, therefore, dwell on the curious cases of dimorphism; cases in which the same definite chemical compound of the same elements appears to have two different forms; thus the carbonate of lime has two forms, calc-spar and arragonite, which belong to different systems of

crystallization. Such facts may puzzle us; but they hardly interfere with any received general truths, because we have as yet no truths of very high order respecting the connexion of chemical constitution and crystalline form. Dimorphism does not interfere with isomorphism; the two classes of facts stand at the same stage of inductive generalization, and we wait for some higher truth, which shall include both, and rise above them.

[2nd Ed.] [For additions to our knowledge of the Dimorphism of Bodies, see Professor Johnstone's valuable Report on that subject in the Reports of the British Association for 1837. Substances have also been found which are trimorphous. We owe to Professor Mitscherlich the discovery of dimorphism, as well as of isomorphism: and to him also we owe the greater part of the knowledge to which these discoveries have led.]

CHAPTER VII.

ATTEMPTS TO ESTABLISH THE FIXITY OF OTHER PHYSICAL PROPERTIES.—WERNER.

THE reflections from which it appeared, (at the end of the last Book,) that in order to obtain general knowledge respecting bodies, we must give scientific fixity to our appreciation of their properties, applies to their other properties as well as to their crystalline form. And though none of the other properties have yet been referred to standards so definite as that which geometry supplies for crystals, a system has been introduced which makes their measures far more constant and precise than they are to a common undisciplined sense.

The author of this system was Abraham Gottlob Werner, who had been educated in the institutions which the elector of Saxony had established at the mines of Freiberg. Of an exact and methodical intellect, and of great acuteness of the senses, Werner was well fitted for the task of giving fixity to the appreciation of outward impressions; and this he attempted in his Dissertation on the External Characters of Fossils, which was published at Leipzig in 1774. Of the precision of his estimation of such characters, we may judge from the following story, told by his biographer Frisch. One of his companions had received a quantity of pieces of amber, and was relating to Werner, then very young, that he had found in the lot one piece from which he could extract no signs of electricity. Werner requested to be allowed to put his hand in the bag which contained these pieces, and immediately drew out the unelectrical piece. It was yellow chalcedony, which is distinguishable from amber by its weight and coldness.

The principal external characters which were sub-

Werner's Leben, p. 26.

jected by Werner to a systematic examination, were colour, lustre, hardness, and specific gravity. subdivisions of the first character (Colour,) were very numerous; yet it cannot be doubted that if we recollect them by the eye, and not by their names, they are definite and valuable characters, and especially the metallic colours. Breithaupt, merely by the aid of this character, distinguished two new compounds among the small grains found along with the grains of platinum, and usually confounded with them. The kinds of Lustre, namely, glassy, fatty, adamantine, metallic, are, when used in the same manner, equally valuable. Specific Gravity obviously admits of a numerical measure; and the Hardness of a mineral was pretty exactly defined by the substances which it would scratch, and by which it was capable of being scratched.

Werner soon acquired a reputation as a mineralogist, which drew persons from every part of Europe to Freiberg in order to hear his lectures; and thus diffused very widely his mode of employing external characters. It was, indeed, impossible to attend so closely to these characters as the Wernerian method required, without finding that they were more distinctive than might at first sight be imagined; and the analogy which this mode of studying Mineralogy established between that and other branches of Natural History, recommended the method to those in whom a general inclination to such studies was excited. Thus Professor Jameson of Edinburgh, who had been one of the pupils of Werner at Freiberg, not only published works in which he promulgated the mineralogical doctrines of his master, but established in Edinburgh a 'Wernerian Society, having for its object the general cultivation of Natural History.

Werner's standards and nomenclature of external characters were somewhat modified by Mohs, who, with the same kind of talents and views, succeeded him at Freiberg. Mohs reduced hardness to numerical measure by selecting ten known minerals, each harder

FIXITY OF PHYSICAL PROPERTIES.

195

than the other in order, from tale to corundum and diamond, and by making the place which these interests occupy in the list, the numerical measure of the bardness of those which are compared with them. The result of the application of this fixed measurement and nomenclature of external characters will appear in the History of Classification, to which we now proceed.

SYSTEMATIC MINERALOGY.

CHAPTER VIII.

ATTEMPTS AT THE CLASSIFICATION OF MINERALS.

Sect. 1.—Proper object of Classification.

THE fixity of the crystalline and other physical properties of minerals is turned to account by being made the means of classifying such objects. To use the language of Aristotle,1 Classification is the architectonic science, to which Crystallography and the Doctrine of External Characters are subordinate and ministerial, as the art of the bricklayer and carpenter are to that of the architect. But classification itself is useful only as subservient to an ulterior science, which shall furnish us with knowledge concerning things so classified. To classify is to divide and to name, and the value of the Divisions which we thus make, and of the Names which we give them, is this, -that they render exact knowledge and general propositions possible. Now the knowledge which we principally seek concerning minerals is a knowledge of their chemical composition, the general propositions to which we hope to be led are such as assert relations between their intimate constitution and their external attributes. Thus our Mineralogical Classification must always have an eye turned towards Chemistry. We cannot get rid of the fundamental conviction, that the elementary composition of bodies, since it fixes their essence, must determine their properties. Hence all mineralogical arrangements, whether they profess it or not, must be, in effect, chemical; they must have it for their object to bring into view a set of relations, which, whatever else they may be, are at least chemical

Eth. Nicom 1, 2.

relations. We may begin with the outside, but it is only in order to reach the inner structure. We may classify without reference to chemistry; but if we do so, it is only that we may assert chemical propositions with reference to our classification.

But, as we have already attempted to show, we not only may, but we must classify, by other than chemical characters, in order to be able to make our classification the basis of chemical knowledge. In order to assert chemical truths concerning bodies, we must have the bodies known by some tests not chemical. The chemist cannot assert that Arragonite does or does not contain Strontia, except the mineralogist can tell him whether any given specimen is or is not Arragonite. If chemistry be called upon to supply the definitions as well as the doctrines of mineralogy, the science can only consist of identical propositions.

Yet chemistry has been much employed in mineralogical classifications, and, it is generally believed, with advantage to the science: How is this consistent with

what has been said?

To this the answer is, that when this has been done with advantage, the authority of external characters, as well as of chemical constitution, has really been brought into play. We have two sets of properties to compare, chemical and physical, to exhibit the connexion of these is the object of scientific mineralogy. And though this connexion would be most distinctly asserted, if we could keep the two sets of properties distinct, yet it may be brought into view in a great degree, by classifications in which both are referred to as guides. Since the governing principle of the attempts at classification is the conviction that the chemical constitution and the physical properties have a definite relation to each other, we appear entitled to use both kinds of evidence, in proportion as we can best obtain each; and then the general consistency and convenience of our system will be the security for its containing substantial knowledge, though this be not presented in a rigorously logical or systematic form.

Such mixed systems of classification, resting partly on chemical and partly on physical characters, naturally appeared as the earliest attempts in this way, before the two members of the subject had been clearly separated in men's minds, and these systems, therefore, we must first give an account of.

Sect. 2.—Mixed Systems of Classification.

Early Systems. - The first attempts at classifying minerals went upon the ground of those differences of general aspect which had been recognized in the formation of common language; as earths, stones, metals. But such arrangements were manifestly vague and confused; and when chemistry had advanced to power and honour, her aid was naturally called in to introduce a better order. 'Hiarne and Bromell were, as far as I know, says? Cronstedt, the first who founded any mineral system upon chemical principles; to them we owe the three known divisions of the most simple mineral bodies; viz, the calcarei, vitrescentes, and apyri.' But Cronstedt's own Essay towards a System of Mineralogy, published in Swedish in 1758, had perhaps more influence than any other, upon succeeding systems. In this, the distinction of earths and stones, and also of vitrescent and non-vitrescent earths (apyri), is rejected. The earths are classed as calcareous, siliceous, argillaceous, and the like. Again, calenreous earth is pure (calc spar), or united with acid of vitriol (gypsum), or united with the muriatic acid (sal ammoniac), and the like. It is easy to see that this is the method, which, in its general principle, has been continued to our own time. In such methods, it is supposed that we can recognize the substance by its general appearance, and on this assumption, its place in the system conveys to us chemical knowledge concerning it.

But as the other branches of Natural History, and especially Botany, assumed a systematic form, many

mineralogists became dissatisfied with this casual and superficial mode of taking account of external characters; they became convinced, that in Mineralogy as in other sciences, classification must have its system and its rules. The views which Werner ascribes to his teacher, Pabst von Ohain,3 show the rise of those opinions which led through Werner to Mohs: 'He was of opinion that a natural mineral system must be constructed by chemical determinations, and external characters at the same time (methodus mixta); but that along with this, mineralogists ought also to construct and employ what he called an artificial system, which might serve us as a guide (loco tudicis) how to introduce newly discovered fossils into the system, and how to find easily and quickly those already known and introduced.' Such an artificial system containing, not the grounds of classification, but marks for recognition, was afterwards attempted by Mohs, and termed by him the Characteristic of his system.

Werner's System. - But, in the mean time, Werner's classification had an extensive reign, and this was still a mixed system. Werner himself, indeed, never published a system of mineralogy. 'We might almost imagine,' Cuvier says, that when he had produced his nomenclature of external characters, he was affrighted with his own creation; and that the reason of his writing so little after this first essay, was to avoid the shackles which he had imposed upon others. His system was, indeed, made known, both in and out of Germany, by his pupils, but, in consequence of Werner's unwillingness to give it on his own authority, it assumed, in its published forms, the appearance of an extorted secret imperfectly told. A Notice of the Mineralogical Cabinet of Mine-Director Pabet von Ohnin, was, in 1792, published by Karsten and Hoffman, under Werner's direction; and conveyed, by example, his views of mineralogical arrangement, and in 1816 his Doctrine of Classification was surrepti-

Frisch H'erner's Leben, p. 15.
Frisch p. 5a.

^{*} Cuv. El. II 114.

tiously copied from his manuscript, and published in a German Journal, termed *The Hesperus*. But it was only in 1817, after his death, that there appeared *Werner's Last Mineral System*, edited from his papers by Breithaupt and Köhler: and by this time, as we shall soon see, other systems were coming forwards on

the stage.

A very slight notice of Werner's arrangement will suffice to show that it was, as we have termed it, a Mixed System. He makes four great Classes of fossils, Earthy, Saline, Combustible, Metallic the earthy fossils are in eight Genera-Diamond, Zircon, Silica, Alumina, Tale, Lime, Baryta, Hallites. It is clear that these genera are in the main chemical, for chemistry alone can definitely distinguish the different Earths which characterize them. Yet the Wernerian arrangement supposed the distinctions to be practically made by reference to those external characters which the teacher himself could employ with such surpassing skill. And though it cannot be doubted, that the chemical views which prevailed around him had a latent influence on his classification in some cases, he resolutely refused to bend his system to the authority of chemistry. Thus, when he was blamed for having, in opposition to the chemists, placed diamond among the earthy fossils, he persisted in declaring that, mineralogically considered, it was a stone, and could not be treated as anything else.

This was an indication of that tendency, which, under his successor, led to a complete separation of the two grounds of classification. But before we proceed to this, we must notice what was doing at this period.

in other parts of Europe.

Hany's System — Though Werner, on his own principles, ought to have been the first person to see the immense value of the most marked of external characters, crystalline form, he did not, in fact, attach much importance to it. Perhaps he was in some measure fascinated by a fondness for those characters

Frisch, p. 6a.

which he had himself systematized, and the study of which did not direct him to look for geometrical relations. However this may be, the glory of giving to Crystallography its just importance in Mineralogy is due to France, and the Treatise of Hauy, published in 1801, is the basis of the best succeeding works of mineralogy. In this work, the arrangement is professedly chemical; and the classification thus established is employed as the means of enunciating crystallographic and other properties. 'The principal object of this Treatise, says the author,7 'is the exposition and developement of a method founded on certain principles, which may serve as a frame-work for all the knowledge which Mineralogy can supply, aided by the different sciences which can join hands with her and march on the same line.' It is worthy of notice, as characteristic of this period of Mixed Systems, that the classification of Hauy, though founded on principles so different from the Wernerian ones, deviates little from it in the general character of the divisions. Thus, the first Order of the first Class of Hany is Acidiferous Earthy Substances; the first genus is Lime, the species are, Carbonate of Lime, Phosphate of Lime, Fluate of Lime, Sulphate of Lime, and so on.

Other Systems.—Such mixed methods were introduced also into this country, and have prevailed, we may say, up to the present time. The Mineralogy of William Phillips, which was published in 1824, and which was an extraordinary treasure of crystallographic facts, was arranged by such a mixed system, that is, by a system professedly chemical; but, inasmuch as a rigid chemical system is impossible, and the assumption of such a one leads into glaring absurdities, the system was, in this and other attempts of the same kind, corrected by the most arbitrary and lax application of other considerations.

It is a curious example of the difference of national intellectual character, that the manifest inconsistencies

of the prevalent systems, which led in Germany, as we shall see, to bold and sweeping attempts at reform, produced in England a sort of contemptuous despair with regard to systems in general,—a belief that no system could be consistent or useful; and a persuasion that the only valuable knowledge is the accumulation of particular facts. This is not the place to explain how erroneous and unphilosophical such an opinion is. But we may notice that while such a temper prevails among us, our place in this science can never be found in advance of that position which we are now considering as exemplified in the period of Werner and Hauy. So long as we entertain such views respecting the objects of Mineralogy, we can have no share in the fortunes of the succeeding period of its history, to which I now proceed.

CHAPTER IX.

ATTEMPTS AT THE REFORM OF MINERALOGICAL SYS-TEMS. SEPARATION OF THE CHEMICAL AND NATURAL HISTORY METHODS.

Sect. 1.—Natural History System of Mohs.

THE chemical principle of classification, if pursued At random, as in the cases just spoken of, leads to results at which a philosophical spirit revolts, it separates widely substances which are not distinguishable; joins together bodies the most dissimilar, and in hardly any instance does it bring any truth into view. vices of classifications like that of Haay could not long be concealed; but even before time had exposed the weakness of his system, Hauy hunself had pointed out, crearly and without reserve,1 that a chemical system is only one side of the subject, and supposes, as its counterpart, a science of external characters. In the mean time, the Wernerians were becoming more and more in love with the form which they had given to such a science. Indeed, the expertness which Werner and his scholars acquired in the use of external characters, justified some partiality for them. related of him,2 that, by looking at a piece of iron-ore, and possing it in his hand, he was able to tell, almost precisely, the proportion of pure metal which it contained. And in the last year of his life, he had marked out, as the employment of the ensuing winter, the study of the system of Berzelius, with a view to find out the laws of combination as disclosed by external characters. In the same spirit, his pupil Breithaupt attempted to discover the ingredients of minerals by their peculiarities of crystallization. The

¹ See his Disc. Prel.

² Frisch, Werner's Leben, p. 78.

J Frisch 3.

⁴ Dresdn, Auswahl, vol. H. p. 97.

persuasion that there must be some connexion between composition and properties, transformed itself, in their minds, into a belief that they could seize the nature of

the connexion by a sort of instinct.

This opinion of the independency of the science of external characters, and of its sufficiency for its own object, at last assumed its complete form in the bold attempt to construct a system which should borrow nothing from chemistry. This attempt was made by Frederick Mohs, who had been the pupil of Werner. and was afterwards his successor in the school of Freiberg; and who, by the acute and methodical character of his intellect, and by his intimate knowledge of minerals, was worthy of his predecessor. Rejecting altogether all divisions of which the import was chemical, Mohs turned for guidance, or at least for the light of analogy, to botany. His object was to construct a Natural System of mineralogy. What the conditions and advantages of a natural system of any province of nature are, we must delay to explain till we have before us, in botany, a more luminous example of such a scheme. But further; in mineralogy, as in botany, besides the Natural System, by which we form our classes, it is necessary to have an Artificial System, by which we recognize them ;—a principle which, we have seen, had already taken root in the school of Freiberg. Such an artificial system Mohs produced in his (haracteristic of the Mineral Kingdom, which was published at Dresden in 1820; and which, though extending only to a few pages, excited a strong interest in Germany, where men's minds were prepared to interpret the full import of such a work. Some of the traits of such a 'Characteristic' had, indeed, been previously drawn by others; as for example, by Hany, who notices that each of his Classes has peculiar characters. For instance, his First Class (acidiferous substances,) alone possesses these combinations of properties: 'division into a regular octohedron, without being able to scratch glass; specific gravity above 3'5, without being able to scratch glass.' The extension of such characters into a scheme which should

exhaust the whole mmeral kingdom, was the under-

taking of Mohs.

Such a collection of marks of classes, implied a classification previously established, and accordingly, Mohs had created his own mineral system. His aim was to construct it, as we shall hereafter see that other natural systems are constructed, by taking into account all the resemblances and differences of the objects classified. It is obvious that to execute such a work. implied a most intimate and universal acquaintance with minerals, -a power of combining in one vivid survey the whole mineral kingdom To illustrate the spirit in which Professor Mohs performed his task, I hope I may be allowed to refer to my own intercourse with him. At an early period of my mineralogical studies, when the very conception of a Natural System was new to me, he, with great kindliness of temper, allowed me habitually to propose to him the scruples which arose in my mind, before I could admit principles which appeared to me then so vague and indefinite; and answered my objections with great patience and most instructive clearness. Among other difficulties, I one day propounded to him this, - 'You have published a Treatise on Mineralogy, in which you have described all the important properties of all known minerals. On your principles, then, it ought to be possible, merely by knowing the descriptions in your book, and without seeing any minerals, to construct a natural system; and this natural system ought to turn out identical with that which you have produced, by so careful an examination of the minerals themselves." He pondered a moment, and then he answered, 'It is true, but what an enormous imagination (rinbildungskraft, power of inward imagining,) a man must have for such a work! Vividness of conception of sensible properties, and the steady intuition (annehanung) of objects, were deemed by him, and by the Wernerian school in general, to be the most essential conditions of complete knowledge.

It is not necessary to describe Moha's system in detail; it may sufficiently indicate its form to state

Mohs not only aimed was also ambitious of gi which should accord wit was too bold to succeed. clature was much needed too, that it was reasonable classification, an improved been so happily obtained But besides th Linnæus. he had not prepared his temperance and skill of th He called upon mineralog almost every mineral with and the proposed appellat brous form, as the above o Such names could have only after a general and system; and the system di degree, that evidence which in the belief of philosoph results with those of Chen finally of the fortunes of th will say something of the made about the same time Mineralogy from

of the present century had been distinguished by the establishment of the theory of definite proportions, and by discoveries which pointed to the electro-chemical theory, it could not appear presumption to suppose, that the classification of bodies, so far as it depended on chemistry, might be presented in a form more complete and scientific than at any previous time.

The attempt to do this was made by the great Swedish chemist Jacob Berzehus. In 1816, he published his Essay to establish a purely Scientific System of Mineralogy, by means of the Application of the Electro-chemical Theory and the Chemical Doctrine of Definite Proportions. It is manifest that, for minerals which are constituted by the law of Definite Proportions, this constitution must be a most essential part of their character. The electro-chemical theory was called in aid, in addition to the composition, because, distinguishing the elements of all compounds as electropositive and electro-negative, and giving to every element a place in a series, and a place defined by the degree of these relations, it seemed to afford a rigorous and complete principle of arrangement. Accordingly, Berzelius, in his First System, arranged minerals according to their electro-positive element, and the elements according to their electro-positive rank; and supposed that he had thus removed all that was arbitrary and vague in the previous chemical systems of mineralogy.

Though the attempt appeared so well justified by the state of chemical science, and was so plausible in its principle, it was not long before events showed that there was some fallacy in these specious appearances. In 1820, Mitscherlich discovered Isomorphism: by that discovery it appeared that bodies containing very different electro-positive elements could not be distinguished from each other, it was impossible, therefore, to put them in distant portions of the classification;—and thus the first system of Berzelius crumbled to pieces.

But Berzelius did not so easily resign his project. With the most unhesitating confession of his first failure, but with undaunted courage, he again girded

himself to the task of rebuilding his edifice. Defeated at the electro-positive position, he now resolved to make a stand at the electro-negative element. In 1824, he published in the Transactions of the Swedish Academy, a Memoir On the Alterations in the Chemical Mineral System, which necessarily follow from the property exhibited by I somorphous Bodies, of replacing each other in given proportions. The alteration was, in fact, an inversion of the system, with an attempt still to preserve the electro-chemical principle of arrangement. Thus, instead of arranging metallic minerals according to the metal, under iron, copper, &c., all the sulphurets were classed together, all the oxides together, all the sulphates together, and so in other respects. That such an order was a great improvement upon the preceding one, cannot be doubted, but we shall see, I think, that as a strict scientific system it was not successful. The discovery of isomorphism, however, naturally led to such attempts. Thus Gmelin also, in 1825, published a mineral system, which, like that of Berzelius, founded its leading distinctions on the electro-negative, or, as it was sometimes termed, the formative element of bodies; and, besides this, took account of the numbers of atoms or proportions which appear in the composition of the body; distinguishing, for instance, Silicates, as simple silicates, double silicates, and so on, to quintuple silicate (Pechstein) and sextuple silicate (Perlstein). In like manner, Nordenskield devised a system resting on the same bases, taking into account also the crystalline form. In 1824, Beudant published his Traité Elémentaire de Minéralogie, in which he professes to found his arrangement on the electro-negative element, and on Ampère's circular arrangement of elementary substances. Such schemes exhibit rather a play of the mere logical faculty, exercising itself on assumed principles, than any attempt at the real interpretation of nature. Other such pure chemical systems may have been published, but it is not necessary to accumulate instances. I proceed to consider their result.

⁵ Zeitsch, der Min. 1825, p. 415.

REFORM OF MINERALOGICAL SYSTEMS. 209

Sect. 3.—Failure of the Attempts at Systematic Reform.

Ir may appear presumptuous to speak of the failure of those whom, like Berzelius and Mohs, we acknowledge as our masters, at a period when, probably, they and some of their admirers still hold them to have succeeded in their attempt to construct a consistent system. But I conceive that my office as an historian requires me to exhibit the fortunes of this science in the most distinct form of which they admit, and that I cannot evade the duty of attempting to seize the true aspect of recent occurrences in the world of science. Hence I venture to speak of the failure of both the attempts at framing a pure scientific system of mineralogy, - that founded on the chemical, and that founded on the natural-history principle; because it is clear that they have not obtained that which alone we could, according to the views here presented, consider as success. - a coincidence of each with the other. A Chemical System of arrangement, which should bring together, in all cases, the substances which come nearest each other in external properties: -a Naturalhistory System, which should be found to arrange bodies in complete accordance with their chemical constitution:-if such systems existed, they might, with justice, claim to have succeeded. Their agreement would be their verification. The interior and the exterior system are the type and the antitype, and their entire correspondence would establish the mode of interpretation beyond doubt. But nothing less than this will satisfy the requisitions of science. And when, therefore, the chemical and the natural-history system, though evidently, as I conceive, tending towards each other, are still far from coming together, it is impossible to allow that either method has been successful in regard to its proper object.

But we may, I think, point out the fallacy of the principles, as well as the imperfection of the results, of both of those methods. With regard to that of Berzelius, indeed, the history of the subject obviously

estimate the value of the characters of a plant by their bearing on its functions,—by their place in its organization. In an unorganic body, the chemical constitution is the law of its being, and we shall never succeed in framing a science of such bodies but by studiously directing our efforts to the interpretation of that law.

On these grounds, then, I conceive, that the bold attempts of Mohs and of Berzelius to give new forms to mineralogy, cannot be deemed successful in the manner in which their authors aspired to succeed. Neither of them can be marked as a permanent reformation of the science. I shall not inquire how far they have been accepted by men of science, for I conceive that their greatest effect has been to point out improvements which might be made in mineralogy without going the whole length either of the pure chemical, or of the pure natural-history system.

Sect. 4 .- Return to Mixed Systems with Improvements.

In spite of the efforts of the purists, mineralogists returned to mixed systems of classification; but these systems are much better than they were before such efforts were made.

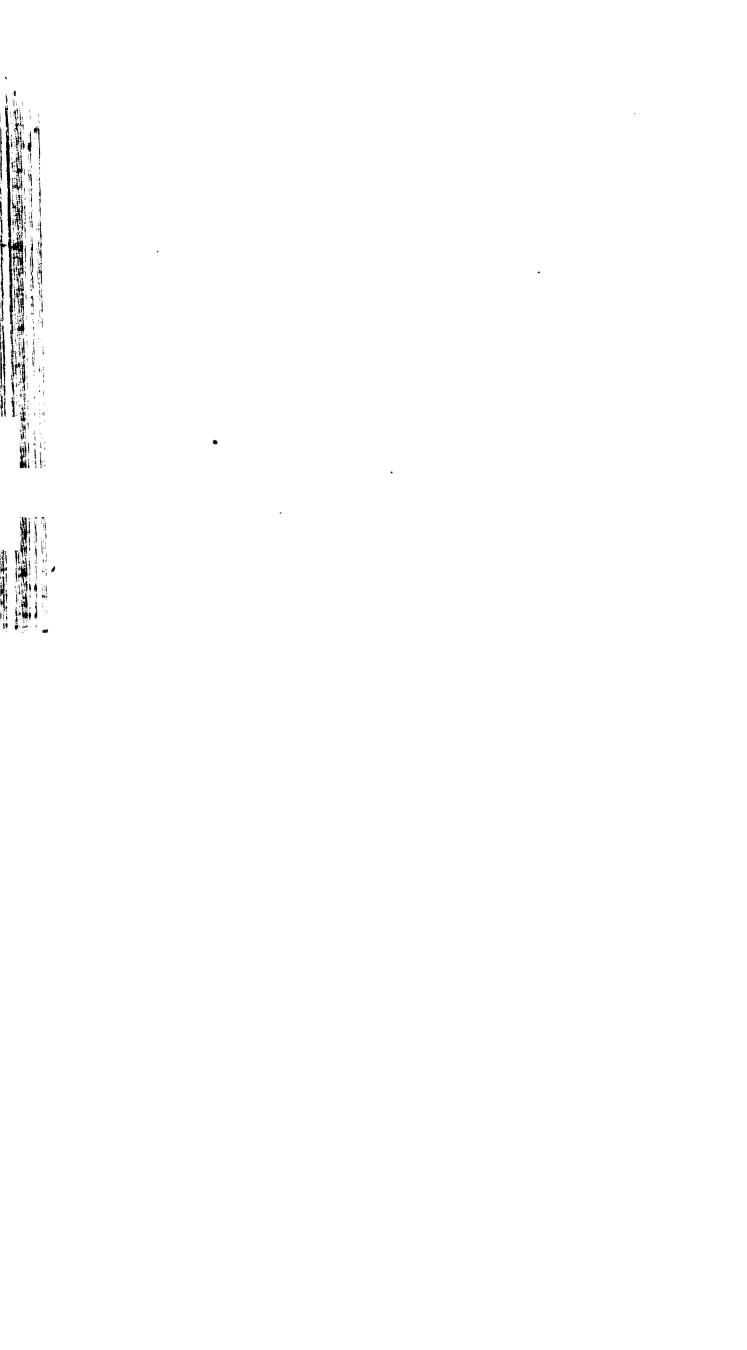

The Second System of Berzelius, though not tenable in its rigorous form, approaches far nearer than any previous system to a complete character, bringing together like substances in a large portion of its extent. The System of Mohs also, whether or not unconsciously swayed by chemical doctrines, forms orders which have a community of chemical character; thus, the minerals of the order Haloide are salts of oxides, and those of the order Pyrites are sulphurets of metals. Thus the two methods appear to be converging to a common center; and though we are unable to follow either of them to this point of union, we may learn from both in what direction we are to look for it. If we regard the best of the pure systems hitherto devised as indications of the nature of that system, perfect both as a chemical and as a natural-history system, to which a more complete condition of mineralogical knowledge

may lead us, we may obtain, even at present, a tolerably good approximation to a complete classification; and such a one, if we recollect that it must be imperfect, and is to be held as provisional only, may be of no small value and use to us.

The best of the mixed systems produced by this compromise again comes from Freiberg, and was published by Professor Naumann in 1828. Most of his orders have both a chemical character and great external resemblances. Thus his Haloides, divided into Unmetallic and Metallic, and these again into Hydrous and Anhydrous, give good natural groups. The most difficult minerals to arrange in all systems are the siliceous ones. These M. Naumann calls Silicides, and subdivides them into Metallic, Unmetallic, and Amphoteric or mixed; and again, into Hydrous and Anhydrous. Such a system is at least a good basis for future researches, and this is, as we have said, all that we can at present hope for. And when we recollect that the natural-history principle of classification has begun, as we have already seen, to make its appearance in our treatises of chemistry, we cannot doubt that some progress is making towards the object which I have pointed out. But we know not yet how far we are from the end. The combination of chemical, crystallographical, physical and optical properties into some lofty generalization, is probably a triumph reserved for future and distant years.

Conclusion.—The history of Mineralogy, both in its successes and by its failures, teaches us this lesson;—that in the sciences of classification, the establishment of the fixity of characters, and the discovery of such characters as are fixed, are steps of the first importance in the progress of these sciences. The recollection of this maxim may aid us in shaping our course through the history of other sciences of this kind; in which, from the extent of the subject and the mass of literature belonging to it, we might at first almost despair of casting the history into distinct epochs and periods. To the most prominent of such sciences, Botany, I now

proceed.

INTRODUCTION.

TE now arrive at that study which offers the most copious and complete example of the sciences of classification, I mean Botany. And in this case, we have before us a branch of knowledge of which we may say, more properly than of any of the sciences which we have reviewed since Astronomy, that it has been constantly advancing, more or less rapidly, from the infancy of the human race to the present day. One of the reasons of this resemblance in the fortunes of two studies so widely dissimilar, is to be found in a simplicity of principle which they have in common; the ideas of Likeness and Difference, on which the knowledge of plants depends, are, like the ideas of Space and Time, which are the foundation of astronomy, readily apprehended with clearness and precision, even without any peculiar culture of the intellect. But another reason why, in the history of Botany, as in that of Astronomy, the progress of knowledge forms an unbroken line from the earliest times, is precisely the great difference of the kind of knowledge which has been attained in the two cases. In Astronomy, the discovery of general truths began at an early period of civilization; in Botany, it has hardly yet begun, and thus, in each of these departments of study, the lore of the ancient is homogeneous with that of the modern times, though in the one case it is science, in the other, the absence of science, which pervades all The resemblance of the form of their history arises from the diversity of their materials.

I shall not here dwell further upon this subject, but proceed to trace rapidly the progress of *Systematic* Botany, as the classificatory science is usually denominated, when it is requisite to distinguish between that and Physiological Botany. My own imperfect acquaintance with this study admonishes me not to venture into its details, further than my purpose absolutely requires. I trust that, by taking my views principally from writers who are generally allowed to possess the best insight into the science, I may be able to draw the larger features of its history with tolerable correctness; and if I succeed in this, I shall attain an object of great importance in my general acheme.

CHAPTER I.

IMAGINARY KNOWLEDGE OF PLANTS.

THE apprehension of such differences and resemblances as those by which we group together and discriminate the various kinds of plants and animals, and the appropriation of words to mark and convey the resulting notions, must be presupposed, as essential to the very beginning of human knowledge. In whatever manuer we imagine man to be placed on the earth by his Creator, these processes must be conceived to be, as our Scriptures represent them, contemporaneous with the first exertion of reason, and the first use of speech. If we were to indulge ourselves in framing a hypothetical account of the origin of language, we should probably assume as the first-formed words, those which depend on the visible likeness or unlikeness of objects; and should arrange as of subsequent formation, those terms which imply, in the mind, acts of wider combination and higher abstraction. At any rate, it is certain that the names of the kinds of vegetables and animals are very abundant even in the most uncivilized stages of man's career. Thus we are informed that the inhabitants of New Zealand bave a distinct name of every tree and plant in their island, of which there are six or seven hundred or more different kinds. In the accounts of the rudest tribes, in the earliest legends, poetry, and literature of nations, pines and oaks, roses and violets, the olive and the vine, and the thousand other productions of the earth, have a place, and are spoken of in a manner which assumes, that in such kinds of natural objects, permanent and infallible distinctions had been observed and universally recognized.

For a long period, it was not suspected that any ambiguity or confusion could arise from the use of such terms; and when such inconveniences did occur, (as even in early times they did,) men were far from

Yute a New Zealand, p. 238

divining that the proper remedy was the construction of a science of classification. The loose and insecure terms of the language of common life retained their place in botany, long after their defects were severely felt: for instance, the vague and unscientific distinction of vegetables into trees, shrubs, and herbs, kept its

ground till the time of Linnaus.

While it was thus imagined that the identification of a plant, by means of its name, might properly be trusted to the common uncultured faculties of the mind, and to what we may call the instinct of language, all the attention and study which were bestowed on such objects, were naturally employed in learning and thinking upon such circumstances respecting them as were supplied by any of the common channels through which knowledge and opinion flow into men's minds.

The reader need hardly be reminded that in the earlier periods of man's mental culture, he acquires those opinions on which he loves to dwell, not by the exercise of observation subordinate to reason; but, far more, by his fancy and his emotions, his love of the marvellous, his hopes and fears. It cannot surprize us, therefore, that the earliest love concerning plants which we discover in the records of the past, consists of mythological legends, marvellous relations, and extraordinary medicinal qualities. To the lively fancy of the Greeks, the Narcissus, which bends its head over the stream, was originally a youth who in such an attitude became enamoured of his own beauty: the hyacinth,2 on whose petals the notes of grief were traced (AI, AI,) recorded the sorrow of Apollo for the death of his favourite Hyacinthus: the beautiful lotus of India, which floats with its splended flower on the surface of the water, is the chosen seat of the goddess Lackshmi, the daughter of Ocean.4 In Egypt, too,5

² Nelumbium speciosum.

⁴ Sprengel, Geschichte der Botanik, 1. 27.

Oxiris awam on a lotus-leaf, and Harpocrates was cradled in one. The lotus-eaters of Homer lost immediately their love of home. Every one knows how easy it would be to accumulate such tales of wonder or religion.

These who attended to the effects of plants, might discover in them some medicinal properties, and might easily imagine more; and when the love of the marvellous was added to the hope of health, it is easy to believe that men would be very credulous. We need not dwell upon the examples of this. In Pliny's Introduction to that book of his Natural History which treats of the medicinal virtues of plants, he says,6 Antiquity was so much struck with the properties of herbs, that it affirmed things incredible. Xanthus, the historian, says, that a man killed by a dragon, will be restored to life by an herb which he calls balin, and that Thylo, when killed by a dragon, was recovered by the same plant. Democritus asserted, and Theophrastus believed, that there was an herb, at the touch of which, the wedge which the woodman had driven into a tree would leap out again. Though we cannot credit these stories, most persons believe that almost anything might be effected by means of herbs, if their virtues were fully known. How far from a reasonable estimate of the reality of such virtues were the persons who entertained this belief, we may judge from the many superstitious observances which they associated with the gathering and using of medicinal plants, Theophrastus speaks of these:7 'The drug-sellers and the rhizotomists (root cutters) tell us, he says, 'some things which may be true, but other things which are merely soleinn quackery;" thus, they direct us to gather some plants, standing from the wind, and with our bodies anomited; some by night, some by day, some before the sun falls on them. So far there may be something in their rules. But others are too fantastical and far-fetched. It is, perhaps, not absurd to use a

CHAPTER IL

UNSYSTEMATIC KNOWLEDGE OF PLANTS.

STEP was made towards the formation of the A Science of Plants, although undoubtedly a slight one, as soon as men began to collect information concerning them and their properties, from a love and reverence for knowledge, independent of the pasnon for the marvellous and the impulse of practical utility. This step was very early made. The 'wisdom' of Solomon, and the admiration which was bestowed upon it, prove, even at that period, such a working of the speculative faculty; and we are told, that among other evidences of his being 'wiser than all men,' 'he spake of trees, from the cedar-tree that is in Lebanon even unto the hyssop that springeth out of the wall.' 1 The father of history, Herodotus, shows us that a taste for natural history had, in his time, found a place in the minds of the Greeks. In speaking of the luxuriant vegetation of the Babylonian plain, he is so far from desiring to astonish merely, that he says, 'the blades of wheat and barley are full four fingers wide; but as to the size of the trees which grow from millet and sesame, though I could mention it, I will not; knowing well that those who have not been in that country will hardly believe what I have said already.' He then proceeds to describe some remarkable circumstances respecting the fertilization of the date-palms in Assyria.

This curious and active spirit of the Greeks led rapidly, as we have seen in other instances, to attempts at collecting and systematizing knowledge on almost every subject: and in this, as in almost every other department, Aristotle may be fixed upon, as the representative of the highest stage of knowledge and system which they ever attained. The vegetable kingdom, like every other province of nature, was one of

^{1 1} Kings 1v. 33.

the fields of the labours of this universal philosopher. But though his other works on natural history have come down to us, and are a most valuable monument of the state of such knowledge in his time, his Treatise on Plants is lost. The book De Plantis, which appears with his name, is an imposture of the middle ages, full

of errours and absurdaties.3

His disciple, friend, and successor, Theophrastus of Eresos, is, as we have said already, the first great writer on botany whose works we possess; and, as may be said in most cases of the first great writer, he offers to us a richer store of genuine knowledge and good sense than all his successors. But we find in him that the Greeks of his time, who aspired, as we have said, to collect and systematize a body of information on every subject, failed in one half of their object, as far as related to the vegetable world. Their attempts at a systematic distribution of plants were altogether futile. Although Aristotle's divisions of the animal kingdom are, even at this day, looked upon with admiration by the best naturalists, the arrangements and comparisons of plants which were contrived by Theophrastus and his successors, have not left the slightest trace in the modern form of the science, and, therefore, according to our plan, are of no importance in our history. And thus we can treat all the muscellaneous information concerning vegetables which was accumulated by the whole of this school of writers, in no other way than as something antecedent to the first progress towards systematic knowledge.

The information thus collected by the unsystematic writers is of various kinds; and relates to the economical and medicinal uses of plants, their habits, mode of cultivation, and many other circumstances: it frequently includes some description; but this is always extremely imperfect, because the essential conditions of description had not been discovered. Of works composed of materials so heterogeneous, it can be of little use to produce specimens; but I may

Mirbel, Botanique, il. 305.

gnote a few words from Theophrastus, which may berve to connect him with the future history of the science, as bearing upon one of the many problems respecting the identification of ancient and modern plants. It has been made a question whether the following description does not refer to the potato. He is speaking of the differences of roots: 'Some roots,' he says, 'are still different from those which have been described; as that of the arachidan plant, for this bears fruit under-ground as well as above: the fleshy part sends one thick root deep into the ground, but the others, which bear the fruit, are more slender and higher up, and ramified. It loves a sandy soil, and has no leaf whatever.'

The books of Aristotle and Theophrastus soon took the place of the Book of Nature in the attention of the degenerate philosophers who succeeded them. A story is told by Strabo concerning the fate of the works of these great naturalists. In the case of the wars and changes which occurred among the successors of Alexander, the hens of Theophrastus tried to secure to the aselves his books, and those of his master, by burying them in the ground. There the manuscripts suffered much from damp and worms; till Apollonicon, a book collector of those days, purchased them, and attempted, in his own way, to supply what time had obliterate l. When Sylla marched the Roman troops into Athens, he took possession of the library of Apollonicon; and the works which it contained were soon circulated among the learned of Rome and Alexandria, who were thus enabled to Aristotelize? on botany as on other subjects.

The library collected by the Attalic kings of Pergamus, and the Alexandrian Museum, founded and supported by the Ptolemies of Egypt, rather fostered the commentatorial spirit than promoted the increase of any real knowledge of nature. The Romans, in this

^{*} Theoph i 11,

extraordinary store of knowl unwilling was he to have his a interrupted, that, even before and from his litter as he tradictate to his amanuensis, who his hand from the numbness who by the use of gloves.

It has been ingeniously obse traces in the botanical part of the errours which this hurries study produced; and that he have had books read to him apamiss.10 Thus, among several phrastus having said that the rare,11 Pliny, misled by the ai word (spunian, rare), says that and Spain 12 His work has, wit. called the Encyclopædia of An there are few portions of the le which it does not refer. Of the which it consists, no less than six to the twenty-seventh) relate to tion which is collected in these miscellaneous kind; and the aut

distinction, truth and errour, useful knowledge and absurd fables. The declamatory style, and the comprehensive and lofty tone of thought which we have already spoken of as characteristic of the Roman writers, are peculiarly observable in him. manner of his death is well known: it was occasioned by the eruption of Vesuvius, A.D. 79, to which, in his curiosity, he ventured so near as to be sufficiated.

Plmy's work acquired an almost unlimited authority, as one of the standards of botanical knowledge, in the middle ages; but even more than his, that of his contemporary, Pedanius Dioscorides, of Anazarbus in This work, written in Greek, is held by the best judges 13 to offer no evidence that the author observed for himself. Yet he says expressly in his Preface, that his love of natural history, and his military life, have led him into many countries, in which he has had opportunity to become acquainted with the nature of herbs and trees. 14 He speaks of six hundred plants, but often indicates only their names and properties, giving no description by which they can be identified. The main cause of his great reputation in subsequent times was, that he says much of the medicinal virtues of vegetables.

We come now to the ages of darkness and lethargy, when the labit of original thought seems to die away. as the talent of original observation had done before. Commentators and mystics succeed to the philosophical naturalists of better times. And though a new race, altogether distinct in blood and character from the Greek, appropriates to itself the stores of Grecian learning, this movement does not, as might be expected, break the chains of literary slavery. The Arabs bring, to the cultivation of the science of the Greeks, their own oriental habit of submission, their oriental love of wonder; and thus, while they swell the herd of commentators and mystics, they produce

no philosopher.

Yet the Arabs discharged an important function in

Mirbel, \$10.

of the Christian world were r where they formed the Chal celebrated Nestorian school of many offsets from this in var the fifth century, Hibas, Cum the writings of Aristotle into Nestoriaus paid an especial medicine, and were the most works of the Greek physica Khusistan, they became an o who distributed academical 1 public disputations. The calif fame and the wisdom of the summoned some of them to Be for the foundation of a school The value of the skill, the lea. the Nesterians, was so stron allowed by the Mohammedans Christian religion, and intrus the studies of those of the Mc was most cared for. The af Arabic languages made the t easy. The Nestorians trans ancients out of the former is hence there are still

and Cordova in the west. After some time, the Mohumme lans themselves began to translate and extract from their Syriac sources; and at length to write works of their own. And thus arose vast libraries, such as that of Cordova, which contained 250,000 volumes.

The Nestorians are stated to have first established among the Arabs those collections of medicinal substances (Apothera), from which our term Apotherary is taken, and to have written books (Dispensatoria) containing systematic instructions for the employment of these medicaments, a word which long continued to be applied in the same sense, and which we also retain, though in a modified application (Dispensiony).

The directors of these collections were supposed to he intimately acquainted with plants; and yet, in truth, the knowledge of plants owed but little to them, for the Arabic Dioscorides was the source and standard of then knowledge. The flourishing commerce of the Arabans, their numerous and distant parmeys, made them, no doubt, practically acquainted with the productions of lands unknown to the Greeks and Romans. Their Nestorian teachers had established Christianity even as far as China and Malabar, and their travellers mention 17 the camphor of Sumatra, the alo -wood of Socotra near Java, the tea of Caina. But they never learned the art of converting their practical into speculative knowledge. They treat of planes only in so far as their use in medicine is concerned,1 and followed Dioscorides in the description, and even in the order of the plants, except when they arrange them according to the Arabic alphabet. With little clearness of view, they often mistake what they read 19 thus when Dioscorides says that liquiticon grows on the Apennine, a mountain not far from the Alps, Avicenna, misled by a resemblance of the Araoic letters, quotes him as saying that the plant grows on Akabis, a mountain near Egypt.

Grocce in their gennine form, were gradually dispelling the interlectual clouds of the middle ages, yet during the lifte-uth century, botany makes no approach to a scientine form. The greater part of the literature of this subject consisted of Herbals, all of which were formed on the same plan, and appeared under titles such as Hortus, or Ortus Sanitatis. There are, for example, three such German Herbals, with woodcuts, which date about 1490. But an important pecuharity in these works is, that they contain some indigenous species placed side by side with the old ones. In 1516. The Grete Herbal was published in England, also with woodcuts. It contains an account of more than four hundred vegetables, and their products; of which one hundred and fifty are Eughsb, and are no way distinguished from the exotics by the mode in

which they are inserted in the work.

We shall see, in the next Chapter, that when the intellect of Europe began really to apply itself to the observation of nature, the progress towards genuine science soon began to be visible, in this as in other subjects, but before this tendency could operate freely, the history of botany was destined to show, in another instance, how much more grateful to man, even when roused to intelligence and activity, is the study of tradation than the study of nature. When the scholars of Europe had become acquainted with the genuine works of the ancients in the original languages, the pleasure and admiration which they felt, led them to the most zealous endeavours to illustrate and apply what they read. They fell into the errour of supposing that the plants described by Theophrastus, Dioscorides, Pliny, must be those which grew in their own fields. And thus Ruellius, to a French | hysician, who only travelled in the environs of Paris and in Picardy, imagined that he found there the plants of Italy and Greece. The originators of genuine botany in Germany, Brunfels and Tragus (Bock), committed

A tgaburg, (488 Mainz, 1+2) Lubec, 1+24.
→ De Natura Sterpium, 1536.

the same mistake; and hence arose the misapplication of classical names to many genera. The labours of many other learned men took the same direction, of treating the ancient writers as if they alone were the

sources of knowledge and truth.

But the philosophical spirit of Europe was already too vigorous to allow this superstitious erudition to exercise a lasting sway. Leonicenus, who taught at Ferrara till he was almost a hundred years old, and died in 1524,16 disputed, with great freedom, the authority of the Arabian writers, and even of Pluy. He saw, and showed by many examples, how little Pliny lumself knew of nature, and how many errours he had made or transmitted. The same independence of thought with regard to other ancient writers, was manifested by other scholars. Yet the power of ancient authority melted away but gradually Thus Antonius Brassavola, who established on the banks of the Po the first botanical garden of modern times, published in 1536, his Examen omnium Simplanum Medicamentorum; and, as Cuvier says, 7 though he studied plants in rature, his book (written in the Platonic form of dialogue,) has still the character of a commentary on the ancients.

The Germans appear to have been the first to liberate themselves from this thraldom, and to publish works founded mainly on actual observation. The first of the botanists who had this great ment is Otho Brunfels of Mentz, whose work, Herberum Viras Icones, appeared in 1530. It consists of two volumes in folio, with wood-cuts; and in 1532, a German edition was published. The plants which it contains are given without any arrangement, and thus he belongs to the period of unsystematic knowledge. Yet the progress towards the formation of a system manifested itself so immediately in the series of German botanists to which he belongs, that we might with almost equal propriety transfer him to the history of that progress;

to which we now proceed.

CHAPTER III.

FORMATION OF A SYSTEM OF ARRANGEMENT OF PLANTS.

Sect. 1 .- Prelude to the Epoch of Casalpinus.

THE arrangement of plants in the carliest works was either arbitrary, or according to their use, or some other extraneous erroumstance, as in Pliny. This, and the division of vegetables by Dioscorides into aromatic, alimentary, medicinal, rinous, is, as will be easily seen, a merely casual distribution. The Arabian writers, and those of the middle ages, showed still more clearly their insensibility to the nature of system, by adopting an aphabetical arrangement; which was employed also in the Herbals of the sixteenth century. Bruntels, as we have said, adopted no principle of order nor did his successor, Fuchs Yet the latter writer urged his countrymen to put aside their Arabian and barbarous Latin doctors, and to observe the vegetable kingdom for themselves; and he himself set the example of doing this, examined plants with zeal and accuracy, and made above fifteen hundred drawings of them. 1

The difficulty of representing plants in any useful way by means of drawings, is greater, perhaps, than it at first appears. So long as no distinction was made of the importance of different organs of the plant, a picture representing merely the obvious general appearance and larger parts, was of comparatively small value. Hence we are not to wonder at the slighting manner in which Pliny speaks of such records. Those who gave such pictures of plants, he says, 'Cratenas, Dionysius, Metrodorus, have shown nothing clearly, except the difficulty of their undertaking. A picture

¹ His Historia Siepnon was published at Pasil in 1544.

may be mistaken, and is changed and disfigured by copyists; and, without these imperfections, it is not enough to represent the plant in one state, since it has four different aspects in the four seasons of the year'

The diffusion of the habit of exact drawing, especially among the countrymen of Albert Durer and Lucas Cranach, and the invention of wood-cuts and copper plates, remedied some of these defects. Moreover, the conviction gradually arose in men's minds that the structure of the flower and the fruit are the most important circumstances in fixing the identity of the plant. Theophrastus speaks with precision of the organs which he describes, but these are principally the leaves, roots, and stems. Fuchs uses the term opices for the anthers, and glama for the blossom of grasses, thus showing that he had noticed these parts

as generally present.

In the next writer whom we have to mention, we find some traces of a perception of the real resemblances of plants beginning to appear. It is impossible to explain the progress of such views without assuming in the reader some acquaintance with plants, but a very few words may suffice to convey, the requisite notions. Even in the plants which most commonly come to our way, we may perceive instances of the resemblances of which we speak. Thus Mint, Marjoram, Basil, Sage, Lavender, Thyme, Dead-nettle, and many other plants, have a tubular flower, of which the mouth is divided into two lips; hence they are formed into a family, and termed Labiatos. Again, the Stock, the Wall-flower, the Mustard, the Cress, the Lady smock, the Shepherd's-purse, have, among other similarities, their blossoms with four petals arranged crosswise; these are all of the order ('ruciferæ, Other flowers, apparently more complex, still resemble each other, as Daisy, Marigold, Aster, and Chamonale; these belong to the order Compositiv And though the members of each such family may differ widely in their larger parts, their stems and leaves, the close study of nature leads the botanist irresistibly to consider their resemblances as occupying a far more important place than their

differences. It is the general establishment of this conviction and its consequences which we have now to follow.

The first writer in whom we find the traces of an arrangement depending upon these natural resemblances, is Hieronymus Tragus, (Jerom Bock,) a laborious German botanist, who, in 1551, published a herbal. In this work, several of the species included in those natural families to which we have alluded, as for instance, the Labiatse, the Crucifere, the Compositive, are for the most part brought together; and thus, although with many mistakes as to such connexious, a new principle of order is introduced into

the subject.

In pursuing the development of such principles of natural order, it is necessary to recollect that the principles lead to an assemblage of divisions and groups, successively subordinate, the lower to the higher, like the brighdes, regiments, and companies of an army, or the provinces, towns, and parishes of a kingdom. Species are included in Genera, Genera in Families or Orders, and Orders in Classes. The perception that there is some connexion among the species of plants, was the first essential step, the detection of different marks and characters which should give, on the one hand, limited groups, on the other, comprehensive divisions, were other highlyimportant parts of this advance. To point out every successive movement in this progress would be a task of extreme difficulty, but we may note, as the most prominent portions of it, the establishment of the groups which immediately include Species, that is, the formation of Genera, and the invention of a method which should distribute into consistent and distinct divisions the whole vegetable kingdom, that is, the construction of a System.

To the second of these two steps we have no difficulty in assigning its proper author. It belongs to Casalpinus, and marks the first great epoch of this

Sprengel, 1 470.

science. It is less easy to state to what botanist is due the establishment of Genera; yet we may justly assign the greater part of the merit of this invention, as is usually done, to Conrad Gessner of Zurich This eminent naturalist, after publishing his great work on animals, died of the plague in 1505, at the age of forty-nine, while he was preparing to publish a History of Plants, a sequel to his History of Animals. fate of the work thus left unfinished was remark ble. It fell into the hands of his pupil, Gaspard Wolf, who was to have published it, but wanting leisure for the office, sold it to Josehun Camerarius, a physician and botanist of Nurem erg, who made use of the engravings prepared by Gessner, in an Epitone which he published in 1586. The text of Gessner's work, after passing through various hands, was published in 1754 under the title of General Opera Botanica per duo sacula desiderata, dec., but is very mecomplete.

The imperfect state in which Gessner left his botanical labours makes it necessary to seek the exidence of his peculiar views in scattered passages of his correspondence and other works. One of his great merits was, that he saw the peculiar importance of the flower and fruit as affording the characters by which the affinities of plants were to be detected, and that he urged this view upon his contenu oraries. His plates present to us, by the side of each plant, its flower and its fruit, carefully engraved. And in his communications with his botanical correspondents, he repeatedly insists on these parts. Thus in 1505 Le writes to Zuinger concerning some foreign plants which the latter possessed. Tell me if your plants have fruit and flower, as well as stalk and leaves, for those are of much the greater consequence. By these three marks, flower, fruit, and seed, -I find that Saxifraga and Consolida Regalis are related to Aconite. These characters, derived from the fractification (as the assemblage of flower and fruit is called),

³ Cavler, Leçons sur l'Hot des Sciences Naturelles, partie h p 195.

4 Epistolie, fol 1152 see also fol 65b.

are the means by which genera are established, and hence, by the best botanists, Gessner is declared to be the inventor of genera.5

The labours of Gessner in botany, both on account of the untimished state in which he left the application of his principles, and on account of the absence of any principles a unitestly applicable to the whole extent of the vegetable kingdom, can only be considered as a prelude to the epoch in which those defects were supplied. To that epoch we now proceed.

Sect. 2. - Epoch of Casalpinus. - Formation of a System of Arrangement.

IP any one were disposed to question whether Natural History truly belongs to the domain of Inductive Science, whether it is to be prosecuted by the same methods, and requires the same endowments of mind as those which lead to the successful cultivation of the Physical Sciences, -the circumstances under which Botany has made its advance appear fitted to remove auch doubts. The first decided step in this study was merely the construction of a classification of its subjects. We shall, I trust, be able to show that such a classification includes, in reality, the establishment of one general principle, and leads to more. But without here dwelling on this point, it is worth notice

' How are we to understand,' he inquires, that we must proceed from universals to particulars (as Aristotle directs), when particulars are better known 76 Yet he treats the Master with deference, and, as has been observed,7 we see in his great botanical work deep traces of the best features of the Aristotelian school, logic and method; and, indeed, in this work he frequently refers to his Quastiones Peripatetice. His book, entitled De Plantis libri xvi. appeared at Florence in 1583. The aspect under which his task presented itself to his mind appears to me to possess so much interest, that I will transcribe a few of his reflections. After speaking of the splendid multiplicity of the productions of nature, and the confusion which has hitherto prevailed among writers on plants, the growing treasures of the botanical world, he adds. 'In this immense multitude of plants, I see that want which is most felt in any other unordered crowd if such an assemblage be not arranged into brigades like an army, all must be tumult and fluctuation. And this accordingly happens in the treatment of plants: for the mind is overwhelmed by the confused accumulation of things, and thus arise endless mistake and angry altercation' He then states his general view. which, as we shall see, was adopted by his successors. Since all science consists in the collection of similar. and the distinction of dissimilar things, and since the consequence of this is a distribution into genera and species, which are to be natural classes governed by real differences, I have attempted to execute this task in the whole range of plants, -ut si quid pro ingenii

⁵ Quantiones Perspatetica, (1569.) lib. i quast. 1.
7 Cuvier, p. 198. b Decheatio, 22.

muitate in hujusmodi studio profecerim, ad commutilitatem proferam.' We see here how clearly fans for himself the credit of being the first to the this task of arrangement.

ier certain preparatory speculations, he says,9 now endeavour to mark the kinds of plants by ial circumstances in the fructification.' He then res, ' In the constitution of organs three things minly important—the number, the position, the And he then proceeds to exemplify this: have under one flower, one seed, as Amygdala, seed-receptacle, as Rosa; or Two seeds, as Feruor Two seed-receptucles, as Nasturtuum; or three, Tithymalum kind have THREE seeds, the Bulba-TREE receptacles; or four, as Marribum, FOUR Siler Fot R receptucles; or more, as ('coracea, conver have MORE seeds, Pinus, MORE receptacles." will be observed that we have here ten classes out by means of number alone, added to the gration of whether the seed is alone in its coverin a cherry, or contained in a receptacle with others, as in a beiry, pod, or capsule. Several cas divisions are, however, further subdivided ing to other circumstances, and especially accordthe vital part of the seed, which he called the (cor10), is situated in the upper or lower part of sed. As our object here is only to indicate the ple of the method of Casalpinus, I need not ar dwell on the details, and still less on the defects ich it is distigured, as, for instance, the retention old distinction of Trees, Shrubs, and Herbs.

nome persons it may appear that this arbitrary action of the vegetable kingdom, according to camber of parts of a particular kind, cannot to be spoken of as a great discovery. And if, the distribution had been arbitrary, this would been true; the real merit of this and of every system is, that while it is artificial in its form, it that in its results. The plants which are asso-

Idb. i c, 13, 14.

ciated by the arrangement of Cæsalpinus, are those which have the closest resemblances in the most esential points. Thus, as Lunaeus says, though the first in attempting to form natural orders, he observed as many as the most successful of later writers. Thus his Legumina 11 correspond to the natural order Leguminosa, his genus Ferulaceum! to the Umbellata: his Bulbaceæ13 to Liliaceæ, his Anthemides 14 to the Composite, in like manner, the Boraginea are brought together, la and the Labrata. That such assemblages are produced by the application of his principles, is a sufficient evidence that they have their foundation in the general laws of the vegetable world. If this had not been the case, the mere application of number or figure alone as a standard of arrangement, would have produced only intolerable anomalies. If, for instance, Cæsalpinus had arranged plants by the number of flowers on the same stalk, he would have separated individuals of the same species, if he had distributed them according to the number of leasets which compose the leaves, he would have had to place far asunder different species of the same genus. Or, as he houself Bays, 16 . If we make one genus of those which have a round root, as Rapum, Aristolechia, Cyclaminus, Aton. we shall separate from this genus those which most agree with it, as Napum and Raphanum, which resemble Rapum, and the long Aristolochia, which resembles the round; while we shall join the most remote kinds, for the nature of Cyclaminus and Rapurs is altogether diverse in all other respects. Or if we attend to the differences of stalk, so as to make one genus of those which have a naked stalk, as the Junci. Cape, Aphaca, along with Cicoracea, Viola, we shall still connect the most unlike things, and disjoin the closest affinities. And if we note the differences of leaves, or even flowers, we fall into the same difficulty; for many plants very different in kind have leaved very similar, as Polygonum and Hypericum, Ernes

I. Lib. vi.
 II Lib. vii.
 II Lib. vii.
 II Lib i. cap. xli. p. 25.

and Sesamois, Apium and Ranunculus; and plants of the same genus have sometimes very different leaves, as the several species of Ranunculus and of Lactuca. Nor will colour or shape of the flowers help us better; for what has Vitis in common with Œnanthe, except the resemblance of the flower? He then goes on to say, that if we seek a too close coincidence of all the characters we shall have no Species; and thus shows us that he had clearly before his view the difficulty which he had to attack, and which it is his glory to have overcome, that of constructing Natural Orders.

But as the principles of Cæsalpinus are justified, on the one hand, by their leading to Natural Orders, they are recommended on the other by their producing a System which applies through the whole extent of the vegetable kingdom. The parts from which he takes his characters must occur in all flowering-plants, for all such plants have seeds. And these seeds, if not very numerous for each flower, will be of a certain definite number and orderly distribution. And thus every plant will fall into one part or other of the same

system.

It is not difficult to point out, in this induction of Casalpinus, the two elements which we have so often declared must occur in all inductive processes, the exact acquaintance with facts, and the general and applicable ideas by which these facts are brought together. Casalpique was no mere dealer in intellectual relations or learned traditions, but a laborious and persevering collector of plants and of botanical knowledge. 'For many years,' he says in his Dedication, 'I have been pursuing my researches in various regions, habitually visiting the places in which grew the various kinds of herbs, shrubs, and trees; I have been assisted by the labours of many friends, and by gardens established for the public benefit, and containing foreign plants collected from the most remote regions.' He here refers to the first garden directed to the public study of Botany, which was that of Pisa,17 instituted in 1543, by order of the

Grand Duke Cosmo the First. The management of it was confided first to Lucas Ghini, and afterwards to Cæsalpinus. He had collected also a herbarium of dried plants, which he calls the rudiment of his work. 'Tibi enim,' he says, in his dedication to Francis Medici, Grand Duke of Etruria, 'apid quem extat ejus rudimentum ex plantis libro agglutinatis a me compositum.' And, throughout, he speaks with the most familiar and vivid acquaintance of the various

vegetables which he describes.

But Cæsalpinus also possessed fixed and general views concerning the relation and functions of the parts of plants, and ideas of symmetry and system; without which, as we see in other botanists of his and succeeding times, the mere accumulation of a knowledge of details does not lead to any advance in science. We have already mentioned his reference to general philosophical principles, both of the Perinatetics and of his own. The first twelve chapters of his work are employed in explaining the general structure of plants, and especially that point to which he justly attaches so much importance, the results of the different situation of the cor or corculum of the seed. He shows that if we take the root, or stem, or leaves, or blossom, as our guide in classification, we shall separate plants obviously alike, and approximate those which have merely superficial resemblances. And thus we see that he had in his mind ideas of fixed resemblance and symmetrical distribution, which he sedulously endeavoured to apply to plants; while his acquaintance with the vegetable kingdom enabled him to see in what manner these ideas were not, and in what manner they were, really applicable.

The great ment and originality of Cresalpinus have been generally allowed, by the best of the more modern writers on Botany. Linnaus calls him one of the founders of the science; 'Primus verus systematicus;' and, as if not satisfied with the expression of his admiration in prose, hangs a poetical garland on the

tomb of his hero. The following distich concludes his remarks on this writer:

Quisquis hic extiterit primos concedet honores Cassalpine tibi , primaque serta dabit

and similar language of praise has been applied to him by the best botanists up to Cuvier, 20 who justly terms

his book 'a work of genius.'

Perhaps the great advance made in this science by Casalpinus, is most strongly shown by this; that no one appeared, to follow the path which he had opened to system and symmetry, for nearly a century. Moreover, when the progress of this branch of knowledge was resumed, his next successor, Morison, did not choose to acknowledge that he had borrowed so much from so old a writer, and thus, hardly mentions his name, although he takes advantage of his labours, and even transcribes his words without acknowledgment, as I shall show. The pause between the great invention of Casalpinus, and its natural sequel, the developement and improvement of his method, is so marked, that I will, in order to avoid too great an interruption of chronological order, record some of its circumstances in a separate section.

Sect. 3 .- Stationary Interval.

The method of Cæsalpinus was not, at first, generally adopted. It had, indeed, some disadvantages. Employed in drawing the boundary-lines of the larger divisions of the vegetable kingdom, he had omitted those smaller groups. Genera, which were both most obvious to common botanists, and most convenient in the description and comparison of plants. He had also neglected to give the Synonyms of other authors for the plants apoken of by him; an appendage to botanical descriptions, which the increase of botanical information and botanical books had now rendered indispensable. And thus it happened, that a work, which must always be

considered as forming a great epoch in the science to which it refers, was probably little read, and in a short time could be treated as if it were quite forgotten.

In the mean time, the science was gradually improved in its details. Clusius, or Charles de l'Ecluse, first taught botanists to describe well. 'Before him, says Mirbel, 21 'the descriptions were diffuse, obscure, indistruct; or else concise, incomplete, vague. Clusius introduced exactitude, precision, neatness, elegance, method: he says nothing superfluous, he omits nothing necessary.' He travelled over great part of Europe, and published various works on the more rare of the plants which he had seen. Among such plants, we may note one now well known, the potato; which he describes as being commonly used in Italy in 1586,2 thus throwing doubt, at least, on the opinion which ascribes the first introduction of it into Europe to Sir Walter Raleigh, on his return from Virginia, about the same period. As serving to illustrate, both this point, and the descriptive style of Clusius, I quote, in a note, his description of the flower of this plant."

The addition of exotic species to the number of known plants was indeed going on rapidly during the interval which we are now considering. Francis Hernandez, a Spaniard, who visited America towards the

end of the sixteenth century, collected and described many plants of that country, some of which were afterwards published by Recchi.24 Barnabas Cobo, who went as a missionary to America in 1506, also described plants.25 The Dutch, among other exertions which they made in their struggle with the tyranny of Spain, sent out an expedition which, for a time, conquered the Brazils, and among other fruits of this conquest, they published an account of the natural history of the country. 5 To avoid interrupting the connexion of such labours, I will here carry them on a little further in the order of time. Paul Herman, of Halle, in Saxony, went to the Cape of Good Hope and to Ceylon; and on his return, astonished the botanists of Europe by the vast quantity of remarkable plants which he introduced to their knowledge. 7 Rheede, the Dutch governor of Malabar, ordered descriptions and drawings to be made of many curious species, which were published in a large work in twelve folio volumes. 8 Rumphe, another Dutch consul at Amboyna, 9 laboured with zeal and success upon the plants of the Moluccas. Some species which occur in Madagascar figured in a description of that island composed by the French Commandant Flacourt, 30 Shortly afterwards, Engelbert Kæmpfer, a Westphalian of great acquirements and undaunted courage, visited Persia, Arabia Felix, the Mogul Empire, Ceylon, Bengal, Sumatra, Java, Siam, Japan, Wholer travelled in Greece and Asia Minor; and Sherard, the English consul, published an account of the plants of the neighbourhood of Smyrna.

At the same time, the New World excited also the

curiosity of botanists. Hans Sloane collected the plants of Jamaica; John Banister those of Virginia; William Vernon, also an Englishman, and David Kriege, a Saxon, those of Maryland, two Frenchmen, Surian and Father Plumier, those of Saint Domingo.

We may add that public botanical gardens were about this time established all over Europe. We have already noticed the institution of that of Pisa in 1543; the second was that of Padua in 1545; the next, that of Florence in 1556; the fourth, that of Bologna, 1568; that of Rome, in the Vatican, dates also from

1568.

The first transalpine garden of this kind arose at Leyden in 1577; that of Leipsic in 1580. Henry the Fourth of France established one at Montpellier in 1597. Several others were instituted in Germany; but that of Paris did not begin to exist till 1626, that of Upsal, afterwards so celebrated, took its rise in 1657, that of Amsterdam in 1684. Morison, whom we shall soon have to mention, calls himself, in 1680, the first Director of the Botanical Garden at Oxford.

[2nd Ed | To what is above said of Botanical Gardens and Botanical Writers, between the times of Cæsalpinus and Morison, I may add a few circumstances. The first academical garden in France was that at Montpellier, which was established by Peter Richier de Berleval, at the end of the sixteenth century. About the same period, rare flowers were cultivated at Paris, and pictures of them made, in order to supply the embroiderers of the court-robes with new patterns. Thus agares of the most beautiful flowers in the garden of Peter Robins were published by the court embroiderer Peter Vallet, in 1608, under the title of Le Jardin du Roi Henry IV. But Robins' works were of great service to botany; and his garden assisted the studies of Renealmus (Paul Reneauline), whose Specimen Historiae Plantarum (Paris, 1611.) is highly spoken of by the best botanists. Recently, Mr. Robert Brown has named after him a new genus of Iridea (RENEALMIA); adding, Dixi in memorism Pauli Renealmi, botanici sui ævi accuratissimi, atque

staminum primi scrutatoris; qui non modo corum numerum et situm, sed ctiain filamentorum proportionem passim descripsit, et characterem tetradynamicum siliquosarum perspexit. (Prodromus Flora Nova Hollandia, p. 448)

The oldest Botanical Garden in England is that at Hampton Court, founded by Queen Elizabeth, and much enriched by Charles II. and William III.

(Sprengel, Gesch. d. Bot. vol. ii. p. 96.)]

In the mean time, although there appeared no new system which commanded the attention of the botanical world, the feeling of the importance of the attinities of plants became continually more strong and distinct.

Lobel, who was botanist to James the First, and who published his Stirpium Adversaria Nova in 1571. brings together the natural families of plants more distinctly than his predecessors, and even distinguishes (as Cuvier states, 12) monocotyledonous from dicotyledonous plants; one of the most comprehensive divisionlines of botany, of which succeeding times discovered the value more completely. Fabrus Columna, 34 in 1616, gave figures of the fructification of plants on copper, as Gessner had before done on wood elder Bauhin (John), notwithstanding all that Casalpinus had done, retrograded, in a work published in 1619, into the less precise and scientific distinctions of -trees with nuts; with berries; with acorns; with pods; creeping plants, gourds, &c.: and no clear progress towards a system was anywhere visible among the authors of this period.

While this continued to be the case, and while the materials, thus destitute of order, went on accumulating, it was inevitable that the evils which Cæsalpinus had endeavoured to remedy, should become more and more grievous. 'The nomenclature of the subject "was in such disorder, it was so impossible to determine with certainty the plants spoken of by preceding

^{**} Cuv. Legons, &c. 198.

writers, that thirty or forty different botanists had given to the same plant almost as many different names. Bauhin called by one appellation, a species which Lobel or Matthioli designated by another. There was an actual chaos, a universal confusion, in which it was impossible for men to find their way." We can the better understand such a state of things, from having, in our own time, seen another classificatory science, Mineralogy, in the very condition thus described. For such a state of confusion there is no remedy but the establishment of a true system of classification; which by its real foundation, renders a reason for the place of each species; and which by the fixity of its classes, affords a basis for a standard nomenclature, as finally took place in Botany. But before such a remedy is obtained, men naturally try to alleviate the evil by tabulating the synonyms of different writers, as far as they are able to do so. The task of constructing such a Synonymy of botany at the period of which we speak, was undertaken by Gaspard Bauhin, the brother of John, but nineteen years younger. This work, the Pinax Theatri Botanici, was printed at Basil in 1623. It was a useful undertaking at the time; but the want of any genuine order in the Pinax itself, rendered it impossible that it should be of great permanent utility.

After this period, the progress of almost all the sciences became languid for a while; and one reason of this interruption was, the wars and troubles which prevailed over almost the whole of Europe. The quarrels of Charles the First and his parliament, the civil wars and the usurpation, in England; in France, the war of the League, the stormy reign of Henry the Fourth, the civil wars of the minority of Louis the Thirteenth, the war against the Protestants and the war of the Fronde, in the minority of Louis the Fourteenth; the bloody and destructive Thirty Years' War in Germany; the war of Spain with the United Provinces and with Portugal; —all these dire agitations left men neither leisure nor disposition to direct their best thoughts to the promotion of science. The baser

spirits were brutalized; the better were occupied by high practical aims and struggles of their moral nature. Amid such storms, the intellectual powers of man could not work with their due calmness, nor his intellectual objects shine with their proper lustre.

At length a period of greater tranquillity gleamed forth, and the sciences soon expanded in the sunshine. Botany was not inert amid this activity, and rapidly advanced in a new direction, that of physiology; but before we speak of this portion of our subject, we must complete what we have to say of it as a classificatory science.

Sect. 4.—Sequel to the Epoch of Casalpinus. Further Formation and Adoption of Systematic Arrangement.

Soon after the period of which we now speak, that of the restoration of the Stuarts to the throne of England, systematic arrangements of plants appeared in great numbers, and in a manner such as to show that the minds of botanists had gradually been ripening for this improvement, through the influence of preceding writers, and the growing acquaintance with plants. The person whose name is usually placed first on this list, Robert Morison, appears to me to be much less meritorious than many of those who published very shortly after him; but I will give him the precedence in my narrative. He was a Scotchman, who was wounded fighting on the royalist side in the civil wars of Eugland. On the trumph of the republicans, he withdrew to France, when he became director of the garden of Gaston, Duke of Orléans, at Blois; and there he came under the notice of our Charles the Second; who, on his restoration, summoned Morison to England, where he became Superintendent of the Royal Gardens, and also of the Botanic Garden at Oxford. In 1669, he published Remarks on the Mistakes of the two Bankins, in which he proves that many plants in the Pinax are erroneously placed, and shows considerable talent for appreciating natural families and genera. His great systematic work

appeared from the University press at Oxford in 1680. It contains a system, but a system, Cuvier says, is which approaches rather to a natural method than to a rigorous distribution, like that of his predecessor Casalpinus, or that of his successor Ray. Thus the herbaceous plants are divided into clumbers, leguminous, siliquous, unicapsular, bicapsular, tricapsular, quadricopsular, quinquecapsular; this division being combined with characters derived from the number of petals. But along with these numerical elements, are introduced others of a loose and heterogeneous kind, for instance, the classification of herbs as lactescent and emollient. It is not unreasonable to say, that such a scheme shows no talent for constructing a complete system; and that the most distinct part of it, that dependent on the fruit, was probably borrowed from Casalpinus. That this is so, we have, I think, strong proof; for though Morison nowhere, I believe, mentions Casalpinus, except in one place in a loose enumeration of botanical writers, 36 he must have made considerable use of his work. For he has introduced into his own preface a passage copied literally 31 from the dedication of Casalpinus; which passage we have already quoted (p. 238,) beginning, 'Since all science consists in the collection of similar, and the distinction of dissimilar things.' And that the mention of the original is not omitted by accident, appears from this; that Morison appropriates also the conclusion of the passage, which has a personal reference, 'Conatus sum id præstare in universa plantarum historia, ut si quid pro ingenii mei tenuitate in hujusmodi strutio profecerim, ad communem utilitatem proferrem. That Morison, thus, at so long an interval after the publication of the work of Casalpinus, borrowed from him without acknowledgment, and adopted his system so as to mutilate it, proves that he had neither the temper por the talent of a discoverer; and justifies us withholding from him the credit which belongs to

 ²⁵ Cuv. Leçons, &c. p 486.

⁴ Methodus Plantarum Nova, M. Agri Cantab. p. 87, 1682. Historia Plantarum, 1686.

already seen, I shall give an account, following that great naturalist.43 I confine myself to the ordinary plants, and omit the more obscure vegetables, as mush-

rooms, mosses, ferns, and the like.

Such plants are composite or simple. The composite flowers are those which contain many florets in the same calyx.44 These are subdivided according as they are composed altogether of complete florets, or of half florets, or of a center of complete florets, surrounded by a circumference or ray of demi-florets. Such are the

divisions of the corymbifera, or composita.

In the simple flowers, the seeds are naked, or in a pericarp. Those with naked seeds are arranged according to the number of the seeds, which may be one, two, three, four, or more. If there is only one, no subdivision is requisite: if there are two, Ray makes a subdivision, according as the flower has five petals, or a continuous corolla. Here we come to several natural families. Thus, the flowers with two seeds and five petals are the Umbelliferous plants; the monopetalous flowers with two seeds are the Stellatæ. He founds the division of four seeded flowers on the circumstance of the leaves being opposite, or alternate; and thus agus, we have the natural families of Asperifolia, as Echium, &c., which have the leaves alternate, and the Verticallata, as Salvia, in which the leaves are opposite. When the flower has more than four seeds, he makes no subdivision.

So much for simple flowers with naked seeds. In those where the seeds are surrounded by a pericarp, or fruit, this fruit is large, soft, and fleshy, and the plants are pomiferous; or it is small and juicy, and the fruit

is a berry, as a Gooseberry.

If the fruit is not juicy, but dry, it is multiple or simple. If it be simple, we have the legioninose plants. If it be multiple, the form of the flower is to be attended to. The flower may be monopetalous, or tetrapetalous, or pentapetalous, or with still more divisions.

⁴³ Cuv. Legons Hist, Sc. Nat. 488.

⁴⁴ Involuceum, in modern terminology.

The monopetalous may be regular or irregular; so may the tetrapetalous. The regular tetrapetalous flowers are, for example, the Crucifera, as Stock and Cauliflower: the irregular, are the papilionarcous plants, Peas, Beans, and Vetches; and thus we again come to natural families. The remaining plants are divided in the same way, into those with imperfect, and those with perfect, flowers. Those with imperfect flowers are the Grasses, the Rushes (Junci), and the like; among those with perfect flowers, are the Palmacea, and the Liliacea.

We see that the division of plants is complete as a system, all flowers must belong to one or other of the divisions. Fully to explain the characters and further subdivisions of these families, would be to write a treatise on botany; but it is easily seen that they exhaust the subject as far as they go.

Thus Ray constructed his system partly on the fruit and partly on the flower; or more properly, according to the expression of Linnaus, comparing his earlier with his later system, he began by being a fructicist,

and ended by being a corollist.45 As we have said, a number of systems of arrangement of plants were published about this time, some founded on the fruit, some on the corolla, some on the calvx, and these employed in various ways. Rivinus 46 (whose real name was Bachman,) classified by the flower alone; instead of combining it with the fruit, as Ray had done.47 He had the further merit, of being the first who rejected the old division, of woody, and herbaceous plants; a division which, though at variance with any system founded upon the structure of the plant, was employed even by Tournefort, and only finally expelled by Linnaus.

It would throw little light upon the history of

characters of genera a degree of rigour never before attained, and abstracted them in a separate form. We have already seen that the reception of botanical Systems has depended much on their arrangement into Genera.

Tournefort's success was also much promoted by the author inserting in his work a figure of a flower and fruit belonging to each genus; and the figures, drawn by Auhi et, were of great merit. The study of botany was thus rendered easy, for it could be learned by turning over the leaves of a book. In spite of various defects, these advantages gave this writer an ascendancy which lasted, from 1700, when his book appeared, for more than half a century. For though Linnæus began to publish in 1735, his method and his nomenclature were not generally adopted till 1760.

CHAPTER IV.

THE REFORM OF LINNEUS.

Sect. 1 .- Introduction of the Reform.

LTHOUGH, perhaps, no man of science ever A exercised a greater sway than Linnseus, or had more enthusiastic admirers, the most intelligent botanists always speak of him, not as a great discoverer, but as a judicious and strenuous Reformer. Indeed, in his own lists of botanical writers, he places himself among the 'Reformatores;' and it is apparent that this is the nature of his real claim to admiration; for the doctrine of the sexes of plants, even if he had been the first to establish it, was a point of botanical physiology, a province of the science which no one would select as the peculiar field of Linnaus's glory; and the formation of a system of arrangement on the basis of this doctrine, though attended with many advantages, was not an improvement of any higher order than those introduced by Ray and Tournefort. But as a Reformer of the state of Natural History in his time, Linneus was admirable for his skill, and unparalleled in his success. And we have already seen, in the instance of the reform of mineralogy, as attempted by Mohs and Berzelius, that men of great talents and knowledge may fail in such an undertaking.

It is, however, only by means of the knowledge which he displays, and of the beauty and convenience of the improvements which he proposes, that any one can acquire such an influence as to procure his suggestions to be adopted. And even if original circumstances of birth or position could invest any one with peculiar prerogatives and powers in the republic of science, Karl Linné began his career with no such

dvantages. His father was a poor curate in Smaland, a province of Sweden; his boyhood was spent in poverty and privation; it was with great difficulty that, at the age of twenty-one, he contrived to subsist at the University of Upsal, whither a strong passion for natural history had urged him. Here, however, he was so far fortunate, that Olaus Rudbeck, the professor of botany, committed to him the care of the sotanic Garden. The perusal of the works of vaillant and Patrick Blair suggested to him the idea of an arrangement of plants, formed upon the sexual ingans, the stamens and pistils; and of such an arrangement he published a sketch in 1731, at the age of

But we must go forwards a few years in his life, to to the period to which his most important works colong. University and family quarrels induced him b travel; and, after various changes of scene, he was stiled in Holland, as the curator of the splendid planical garden of George Clifford, an opulent banker. Lere it was that he laid the foundation of his future teatness. In the two years of his residence at arlecamp, he published nine works. The first, the stema Natura, which contained a comprehensive ketch of the whole domain of Natural History, excited neral astonishment, by the acuteness of the observaions, the happy talent of combination, and the clearness the systematic views. Such a work could not fail procure considerable respect for its author. His fortus Cliffortiana and Musa Cliffortiana added to impression. The weight which he had thus equired, he proceeded to use for the improvement of ctany. His Fundamenta Botanica and Bibliotheca lotanica appeared in 1736; his Critica Botanica and enera Plantarum in 1737: his Classes Plantarum 1738; his Species Plantarum was not published till 753; and all these works appeared in many successive ditions, materially modified,

This circulation of his works showed that his labours

wenty-four.

^{&#}x27; Sprengel, il. 232.

were producing their effect. His reputation grew; and he was soon enabled to exert a personal, as well as a literary, influence, on students of natural history. He became Botanist Royal, President of the Academy of Sciences at Stockholm, and Professor in the University of Upsal; and this office he held for thirty-six years with unrivalled credit, exercising, by means of his lectures, his constant publications, and his conversation, an extraordinary power over a multitude of zealous naturalists, belonging to every part of the world.

In order to understand more clearly the nature and effect of the reforms introduced by Linnseus into botany, I shall consider them under the four following heads.—Terminology, Nomenclature, Artificial System, and Natural System.

Sect. 2.—Linnwan Reform of Botanical Terminology.

It must be recollected that I designate as Terminology, the system of terms employed in the description of objects of natural history, while by Nomenclature, I mean the collection of the names of species. The reform of the descriptive part of botany was one of the tasks first attempted by Linnæus; and his terminology was the instrument by which his other improvements were effected.

Though most readers, probably, entertain, at first, a persuacion that a writer ought to content himself with the use of common words in their common sense, and feel a repugnance to technical terms and arbitrary rules of phraseology, as pedantic and troublesome; it is soon found, by the student of any branch of science, that, without technical terms and fixed rules, there can be no certain or progressive knowledge. The loose and infantine grasp of common language cannot hold objects steadily enough for scientific examination, or lift them from one stage of generalization to another. They must be secured by the rigid mechanism of a scientific phraseology. This necessity had been felt in all the sciences, from the earliest periods of their progress. But the conviction had

acted upon so as to produce a distinct note descriptive botanical language. Jung, and already attempted to give rules and thich should answer this purpose; but it was a Fundamenta Botanica appeared, that the aid be said to possess a fixed and complete out.

an account of such a terminology, is, in is a description of a dictionary and grammar, perfore what cannot here be done in detail. work contains about a thousand terms of meaning and application are distinctly s and rules are given, by which, in the use ms, the botanist may avoid all obscurity, nnuecessary prolixity and complexity, and gance and barbarism Of course the greater words which Linnaus thus recognized, iously existed in botanical writers, and bem had been defined with technical prehus Jung4 had already explained what was what a pinnate leaf; what kind of a bunch is a spike, a panicle, an umbel, a corymb, Linnæus extended such distinctions, complete clearness in their separation. Thus, composite leaves are further distinguished punnate, bipinnate, pedate, and so on; eves are abruptly so, or with an odd one, or iril; they are pinnate oppositely, alternately, By, articulately, decursively. Again, the ca, as the mode of assemblage of the flowers y be a tuft, (fasciculus,) a head, (capitulum,) (racemus,) a bunch, (thyrsus,) a panicle, a kin, (amentum,) a corymb, an umbel, a cyms, perticillus.) And the rules which he gives, ten apparently arbitrary and needless, are practice, to be of great service by their fixity ction. By the good fortune of having had with so much delicacy of taste as Linnæus, ion of so much influence, Botany possesses

Phytoscopica, 1679.

⁴ Sprengel, U. 28.

a descriptive language which will long stand as a model for all other subjects.

It may, perhaps, appear to some persons, that such a terminology as we have here described must be enormously cumbrous; and that, since the terms are arbitrarily invested with their meaning, the invention of them requires no knowledge of nature. With respect to the former doubt, we may observe, that technical description is, in reality, the only description which is clearly intelligible; but that technical language cannot be understood without being learnt as any other language is learnt, that is, the reader must connect the terms immediately with his own sensetions and notions, and not mediately, through a verbal explanation; he must not have to guess their meaning, or to discover it by a separate act of interpretation into more familiar language as often as they occur. The language of botany must be the botanist's most familiar tongue. When the student has thus learnt to think in botanical language, it is no idle distinction to tell him that a bunch of grapes is not a cluster; that is, a thyrsus not a raceme. And the terminology of botany is then felt to be a useful implement, not an oppressive burden. It is only the schoolhoy that complains of the irksomeness of his grammar and vocabulary. The accomplished student possesses them without effort or inconvenience.

As to the other question, whether the construction of such a botanical grammar and vocabulary implies an extensive and accurate acquaintance with the facts of nature, no one can doubt who is familiar with any descriptive science. It is true, that a person might construct an arbitrary scheme of distinctions and appellations, with no attention to natural objects; and this is what shallow and self-confident persons often set about doing, in some branch of knowledge with which they are imperfectly acquainted. But the slightest attempt to use such a phraseology leads to confusion; and any continued use of it leads to its demolition. Like a garment which does not fit us, it we attempt to work in it we tear it in pieces.

The formation of a good descriptive language is, in fact, an inductive process of the same kind as those which we have already noticed in the progress of natural history. It requires the discovery of fixed characters, which discovery is to be marked and fixed, like other inductive steps, by appropriate technical terms. The characters must be so far fixed, that the things which they connect must have a more permanent and real association than the things which they leave unconnected. If one bunch of grapes were really a racemus, and another a thyrsus, according to the definition of these terms, this part of the Linnau language would lose its value; because it would no longer enable us to assert a general proposition with respect to one kind of plants.

Sect. 3 .- Linnaan Reform of Botanical Nomenclature,

In the ancient writers each recognized kind of plants had a distinct name. The establishment of Generaled to the practice of designating Species by the name of the genus, with the addition of a 'phrase' to distinguish the species. These phrases, (expressed in Latin in the ablative case,) were such as not only to mark, but to describe the species, and were intended to contain such features of the plant as were sufficient to distinguish it from others of the same genus. But in this way the designation of a plant often became a long and inconvenient assemblage of words. Thus different kinds of Rose were described as,

Rosa campestras, spinis careos, bafora (Rosa alpina.)
Rosa aculeata, folas odoratas subtus rabiginosis (R. eglanteria.)
Rosa carolina fragrans, folas medio tenus serratis (R. carolina.)
Rosa sylvestris vulgaris, flore odorato incarnato (R. canna.)

And several others. The prolixity of these appellations, their variety in every different author, the insufficiency and confusion of the distinctions which they contained, were felt as extreme inconveniences. The attempt of Bauhin to remedy this evil, by a Synonymy, had, as we have seen, failed at the time, for want of any directing principle; and was become still more defective by the lapse of years and the accumulation of

fresh knowledge and new books. Haller had proposed to distinguish the species of each genus by the number 1, 2, 3, and so on; but botanists found that their memory could not deal with such arbitrary abstractions. The need of some better nomenclature was

severely felt.

The remedy which Linnaus finally introduced was the use of trivial names; that is, the designation of each species by the name of the genus along with a single conventional word, imposed without any general rule. Such names are added above in parentheses, to the specimens of the names previously in use. But though this remedy was found to be complete and satisfactory, and is now universally adopted in every branch of natural history, it was not one of the reforms which Linnau at first proposed. Perhaps he did not at first see its full value; or, if he did, we may suppose that it required more self-confidence than he possessed, to set himself to introduce and establish ten thousand new names in the botanical world. Accordingly, the first attempts of Linnaus at the improvement of the nomenclature of botany were, the proposal of fixed and careful rules for the generic name, and for the descriptive phrase. Thus, in his Critica Botanica, he gives many precepts concerning the selection of the names of genera, intended to secure convenience or elegance. For instance, that they are to be single words, he substitutes atropa for bella donna, and leontodon for dens leonis; that they are not to depend upon the name of another genus,6 as acriviola, agrimonoides; that they are not? to be 'sesquipedalia,' and, says he, any word is sesquipedalian to me, which has more than twelve letters, as kalophyllodendron, for which he substitutes calophyllon. Though some of these rules may seem pedantic, there is no doubt that, taken altogether, they tend exceedingly, like the labours of purists in other languages, to exclude extravagance, caprice, and barbarism in botanical speech.

The precepts which he gives for the matter of the

⁵ PMI. Bot. 224.

⁵ Ib. 248, 429.

'descriptive phrase,' or, as it is termed in the language of the Aristotelian logicians, the 'differentia,' are, for the most part, results of the general rule, that the most fixed characters which can be found are to be used; this rule being interpreted according to all the knowledge of plants which had then been acquired. The language of the rules was, of course, to be regulated by the terminology, of which we have already spoken.

Thus, in the Critica Botanica, the name of a plant is considered as consisting of a generic word and a specific phrase; and these are, he says, the right and left hands of the plant. But he then speaks of another kind of name; the trivial name, which is opposed to

the scientific. Such names were, he says, those of his predecessors, and especially of the most ancient of them. Hitherto 10 no rules had been given for their use. He manifestly, at this period, has small regard for them. 'Yet,' he says, 'trivial names may, perhaps, be used on this account,—that the differential often turns out too long to be convenient in common use, and may require change as new species are discovered.

and may require change as new species are discovered. However,' he continues, 'in this work we set such names ande altogether, and attend only to the differentiae.'

Even in the Species Plantarum, the work which gave general currency to these trivial names, he does not seem to have yet dared to propose so great a novelty. They only stand in the margin of the work. I have placed them there, he says in his Preface, that, without circumlocution, we may call every herb by a single name; I have done this without selection, which would require more time. And I beseech all sane botanists to avoid most religiously ever proposing a trivial name without a sufficient specific distinction, lest the science should fall into its former barbarism.

It cannot be doubted, that the general reception of these trivial names of Linnæus, as the current language among botanists, was due, in a very great degree, to the knowledge, care, and skill with which

Phil. Bot. 266.

his characters, both of genera and of species, were constructed. The rigorous rules of selection and expression which are proposed in the Fundamenta Botanus and Critica Botanica, he himself conformed to, and this scrupulosity was employed upon the results of immense labour. 'In order that I might make myself acquainted with the species of plants, he says, in the preface to his work upon them, 'I have explored the Alps of Lapland, the whole of Sweden, a part of Norway, Denmark, Germany, Belgium, England, France: I have examined the Botanical Gardens of Paris, Oxford, Chelsea, Harlecamp, Leyden, Utrecht, Austerdam, Upsal, and others. I have turned over the Herbals of Burser, Hermann, Clifford, Burmann, Oldenland, Gronovius, Royer, Sloane, Sherard, Bobart, Miller, Tournefort, Vaillant, Jussieu, Surien, Beck, Brown, &c.: my dear disciples have gone to distant lands, and sent me plants from thence; Kerlen to Canada, Hasselquist to Egypt, Asbech to China, Toren to Surat, Solander to England, Alstromer to Southern Europe, Martin to Spitzbergen, Pontin to Malabar, Kæhler to Italy, Forskahl to the East, Leefing to Spain, Montin to Lapland: my botanical friends have sent me many seeds and dried plants from various countries: Lagerstrom many from the East Indies; Gronovius most of the Virginian; Gmelin all the Siberian; Burmann those of the Cape.' And in consistency with this habit of immense collection of materials, is his maxim, 1 that 'a person is a better botanist in proportion as he knows more species.' It will easily be seen that this maxim, like Newton's declaration that discovery requires patient thought alone, refers only to the exertions of which the man of genius is conscious; and leaves out of sight his peculiar endowments, which he does not see because they are part of his power of vision. With the taste for symmetry which dictated the Critica Botanica, and the talent for classification which appear in the Genera Plantarum, and the Systema Naturae, a person must undoubtedly rise to higher, steps of classificatory knowledge and skill, as he became

acquainted with a greater number of facts.

The acknowledged superiority of Linneus in the knowledge of the matter of his science, induced other persons to defer to him in what concerned its form; especially when his precepts were, for the most part, recommended strongly both by convenience and elegance. The trivial names of the Species Plantarum were generally received; and though some of the details may have been altered, the immense advantage of the scheme ensures its permanence.

Sect. 4 .- Linnœus's Artificial System.

WE have already seen, that, from the time of Casalpinus, botanists had been endeavouring to frame a arstematic arrangement of plants. All such arrangements were necessarily both artificial and natural; they were artificial, masmuch as they depended upon assumed principles, the number, form, and position of certain parts, by the application of which the whole vegetable kingdom was imperatively subdivided; they were natural, inasmuch as the justification of this division was, that it brought together those plants which were naturally related. No system of arrangement, for instance, would have been tolerated which, in a great proportion of cases, separated into distant parts of the plan the different species of the same genus. As far as the main body of the genera, at least, all systems are natural.

But beginning from this line, we may construct our systems with two opposite purposes, according as we endeavour to carry our assumed principle of division rigorously and consistently through the system, or as we wish to associate natural families of a wider kind than genera. The former propensity leads to an artificial, the latter to a natural method. Each is a System of Plants; but in the first, the emphasis is thrown on the former word of the title, in the other,

on the latter.

The strongest recommendation of an artificial sys-

tem, (besides its approaching to a natural method,) is, that it shall be capable of easy use; for which purpose, the facts on which it depends must be apparent in their relations, and universal in their occurrence. The system of Linnæus, founded upon the number, position, and other circumstances of the stamina and pistils, the reproductive organs of the plants, possessed this ment in an eminent degree, as far as these characters are concerned, that is, as far as the classes and orders. In its further subdivision into genera, its superiority was mainly due to the exact observation and description, which we have already had to notice as talents which

Linnaus peculiarly possessed.

The Lunneau system of plants was more definite than that of Tournefort, which was governed by the corolla, for number is more definite than irregular form. It was more readily employed than any of those which depend on the fruit, for the flower is a more obvious object, and more easily examined. Still, it can hardly be doubted, that the circumstance which gave the main currency to the system of Linnaus was, its physiological signification: it was the Sexual System. The relation of the parts to which it directed the attention, interested both the philosophical faculty and the imagination. And when, soon after the system had become familiar in our own country, the poet of The Botanic Garden peopled the bell of every flower with 'Nymphs' and 'Swains,' his imagery was felt to be by no means forced and far fetched.

The history of the doctrine of the sexes of plants, as a point of physiology, does not belong to this place; and the Linnæan system of classification need not be longer dwelt upon for our present purpose. I will only explain a little further what has been said, that it is, up to a certain point, a natural system. Several of Linnæus's classes are, in a great measure, natural associations, kept together in violation of his own artificial rules. Thus the class Diadelphia, in which, by the system, the filaments of the stamma should be bound together in two parcels, does, in fact, contain many genera which are monadelphous, the filaments of the

in Genista, Spartium, Anthyllis, Lupinus, &c. And why is this violation of rule? Precisely because these genera all belong to the natural tribe of Papilionaceous plants, which the author of the system could not prevail upon himself to tear asunder. Yet in other cases Linnaus was true to his system, to the injury of natural alliances, as he was, for instance, in another portion of this very tribe of Papilionacea, for there are plants which undoubtedly belong to the tribe, but which have ten separate stamens; and these he placed in the order Decandria. Upon the whole, however, he inclines rather to admit transgression of art than of nature.

The reason of this inclination was, that he rightly considered an artificial method as instrumental to the investigation of a natural one; and to this part of his views we now proceed.

Sect. 5 .- Linnaus's Views on a Natural Method.

THE admirers of Linnaus, the English especially, were for some time in the habit of putting his Sexual System in opposition to the Natural Method, which about the same time was attempted in France. And as they often appear to have imagined that the ultimate object of botamcal methods was to know the names of plants, they naturally preferred the Swedish method, which is excellent as a finder. No person, however, who wishes to know botany as a science, that is, as a body of general truths, can be content with making names his ultimate object. Such a person will be constantly and presistably led on to attempt to catch sight of the natural arrangement of plants, even before he discovers, as he will discover by pursuing such a course of study, that the knowledge of the natural arrangement is the knowledge of the essential construction and vital mechanism of plants. He will consider an artificial method as a means of arriving at a natural method. Accordingly, however much some of his followers may have overlooked this, it is what Linnwus himself always held and taught. And though what he executed with regard to this object was but little, 12 the distinct manner in which he presented the relations of an artificial and natural method, may justly be looked upon as one of the great unprovements which to

introduced into the study of his science.

Thus in the ('lasses Plantarum, (1747.) he speaks of the difficulty of the task of discovering the natural orders, and of the attempts made by others. he adds, 'I too have laboured at this, have done something, have much still to do, and shall labour at the object as long as I live.' He afterwards proposed sixty-seven orders, as the fragments of a natural method, always professing their imperfection.13 And in others of his works 14 he lays down some antitheses on the subject after his manner. 'The natural orders teach us the nature of plants; the artificial orders enable us to recognize plants. The natural orders, without a key, do not constitute a Method, the Method ought to be available without a master.'

That extreme difficulty must attend the formation of a Natural Method, may be seen from the very indefinite nature of the Aphorisms upon this subject which Linuxus has delivered, and which the best botanists of succeeding times have assented to. Such are these; -the Natural Orders must be formed by attention, not to one or two, but to all the parts of plants;—the same organs are of great importance in regulating the divisions of one part of the system, and of small importance in another part; 15—the Character does not constitute the Genus, but the Genus the Character; the Character is necessary, not to make the Genus, but to recognize it. The vagueness of these maxims is easily seen; the rule of attending to all the parts, implies, that we are to estimate their relative importance, either by physiological considerations,

15 Phil. Bot. p. 173

¹⁵ The natural orders which he proposed are a bare enumeration of genera, and have not been gene- Project in Ord, Aut. p. xivili. rally followed.

these again lead to arbitrary rules, as, for noc, the superiority of the function of nutrition at of reproduction,) or by a sort of latent natural instinct, which Linneus in some passages seems cognize. 'The Habit of a plant,' he says, 'f' must cretly consulted. A practised botanist will disciply, at the first glance, the plants of different ters of the globe, and yet will be at a loss to tell hat mark he detects them. There is, I know not look,—sinister, dry, obscure in African plants; to and elevated, in the Asiatic, smooth and ful, in the American; stunted and indurated, in theire.'

pin, the rule that the same parts are of very cent value in different Orders, not only leaves us ant of rules or reasons which may enable us to be the marks of different Orders, but destroys tratematic completeness of the natural arrange-

If some of the Orders be regulated by the rand others by the fruit, we may have plants, of the flower would place them in one Order, and that in another. The answer to this difficulty is paxim already stated;—that no Character makes order; and that if a Character do not enable us to paize the Order, it does not answer its purpose, eaght to be changed for another.

servant and not as a master, was a stumblingtin the way of those disciples who looked only commatical and universal rules. One of Linnaus's Paul Dietrich Giseke, has given us a very account of his own perplexity on having this propounded to him, and of the way in which he reled with it. He had complained of the want of ligible grounds, in the collection of natural orders by Linnaus. Linnaus 17 wrote in answer, 'You

ne for the characters of the Natural Orders: I I cannot give them.' Such a reply naturally used Giseke's difficulties. But afterwards, in

¹⁷ Linnai Pralectiones, Pref p. xv.

1771, he had the good fortune to spend some time st Upsal; and he narrates a conversation which he held with the great teacher on this subject, and which I think may serve to show the nature of the difficulty -one by no means easily removed, and by the general reader, not even readily comprehended with distinctness. Giseke began by conceiving that an Order must have that attribute from which its name is derived;that the Umbellate must have their flower disposed in an umbel. The 'mighty master' smiled, 18 and told him not to look at names, but at nature. 'But' (said the pupil) 'what is the use of the name, if it does not mean what it professes to mean? 'It is of small import' (replied Linnaus) 'what you call the Order if you take a proper series of plants and give it some name, which is clearly understood to apply to the plants which you have associated. In such cases is you refer to, I followed the logical rule, of borrowing a name a potiori, from the principal member. Can you' (he added) 'give me the character of any single Order? Gireke. Surely, the character of the Umbellate is, that they have an umbel? Linneus. Good; but there are plants which have an umbel, and are not of the Umbellate.' G. 'I remember. We must therefore add, that they have two naked seeds." L. 'Then, Echinophora, which has only one seed, and Eryngium, which has not an umbel, will not be Umbellatæ; and yet they are of the Order.' G. 'I would place Eryngium among the Aggregate.' L. No; both are beyond dispute Umbellater. Eryngium has an involucrum, five stamins, two pistils, &c. Try again for your Character.' G 'I would transfer such plants to the end of the Order, and make them form the transition to the next Order. Eryngium would connect the Umbellata with the Aggregata.' L. 'Ah! my good friend, the Transition from Order to Order is one thing; the Character of an Order is another. The Transitions I could indicate; but a Character of a Natural Order is impossible. I will not give my

^{18 ·} Subrisit & Maye '

have published. You or some other person, after tenty or after fifty years, will discover them, and see

at I was in the right.'

I have given a portion of this curious conversation, order to show that the attempt to establish Natural ers leads to convictions which are out of the imain of the systematic grounds on which they forces to proceed. I believe the real state of the case be, that the systematist, in such instances, is guided an unformed and undeveloped apprehension of priological functions. The ideas of the form, number figure of parts are, in some measure, overshadowed a superseded by the rising perception of organic vital relations; and the philosopher who aims at Natural Method, while he is endeavouring merely to whore the apartment in which he had placed himself, of Arrangement, is led beyond it, to a point here another light begins, though dimly, to be seen; is brought within the influence of the ideas of manisation and Life.

The sciences which depend on these ideas will be be subject of our consideration hereafter. But what been said may perhaps serve to explain the mowledged and inevitable imperfection of the unvaiological Linnman attempts towards a natural thod 'Artificial Classes are,' Linnaus says, 'a betitute for Natural, till Natural are detected.' But have not yet a Natural Method. 'Nor,' he says, the conversation above cited, 'can we have a Natural thod: for a Natural Method implies Natural Classes d Orders; and these Orders must have Characters.' and they,' he adds, in another place, 19 who, though y cannot obtain a complete Natural Method, arrange ats according to the fragments of such a method, to rejection of the Artificial, seem to me like persons pull down a convenient vaulted room, and set out building another, though they cannot turn the

milt which is to cover it.'

¹⁵ Gen, Plant. in Project. p. xii.

How far these considerations deterred other persons from turning their main attention to a natural method we shall shortly see; but in the mean time, we must complete the history of the Linnean Reform.

Sect. 6.—Reception and Diffusion of the Linnaan Reform.

WE have already seen that Linnaus received, from his own country, honours and emoluments which mark his reputation as established, as early as 1740; and by his publications, his lectures, and his personal communications, he soon drew round him many disciples. whom he impressed strongly with his own doctrines and methods. It would seem that the sciences of classification tend, at least in modern times, more than other sciences, to collect about the chair of the teacher a large body of zealous and obedient pupils. Linneus and Werner were by far the most powerful heads of schools of any men who appeared in the course of the last century. Perhaps one reason of this is, that in these sciences, consisting of such an enormous multitude of species, of descriptive particulars, and of previous classifications, the learner is dependent upon the teacher more completely, and for a longer time, than in other subjects of speculation; he cannot so soon or so easily east off the aid and influence of the master, to pursue reasonings and hypotheses of his Whatever the cause may be, the fact is, that the reputation and authority of Linnaus, in the latter part of his life, were immense. He enjoyed also royal favour, for the King and Queen of Sweden were both fond of natural history. In 1753, Linnæus received from the hand of his sovereign the knighthood of the Polar Star, an honour which had never before been conferred for literary merit, and in 1756, was raised to the rank of Swedish nobility, by the title of Van Linné: and this distinction was confirmed by the Diet in 1762. He lived, honoured and courted, to the age of seventy-one; and in 1778 was buried in the cathedral psal, with many testimonies of public respect and

e Candolle 20 assigns, as the causes of the successes he Linnsean system,—the specific names, —the chabristic phrase,—the fixation of descriptive language, distinction of varieties and species, -- the extenof the method to all the kingdoms of nature, the practice of introducing into it the species most potly discovered. This last course Linnwus con-My pursued; thus making his works the most able for matter, as they were the most convenient m. The general diffusion of his methods over pe may be dated, perhaps, a few years after 1760, the tenth and the succeeding editions of the was Natura were in circulation, professing to de every species of organized beings. s and correspondents effected no less than his a, in giving currency to his system. In Germany,21 as defended by Ludwig, Gesner, Fabricius. But er, whose reputation in physiology was as great as of Linnæus in methodology, rejected it as too y artificial. In France, it did not make any d or extensive progress: the best French botanists at this time occupied with the solution of the great lem of the construction of a Natural Method. though the rhetorician Rousseau, charmed, we suppose, with the elegant precision of the Philois Botanua, declared it to be the most philosophical k he had ever read in his life, Buffon and Adanson, ribers and philosophers of a more ambitious school. a repugnance to the rigorous rules, and limited, finished, undertakings of the Swedish naturalist. resist his criticism and his influence, they armed mselves with dislike and contempt.

in England the Linnman system was very favourably dived. perhaps the more favourably, for being a stly artificial system. For the indefinite and unhed form which almost inevitably clings to a gral method, appears to be peculiarly distasteful to

our countrymen. It might seem as if the suspense and craving which comes with knowledge confesselly incomplete were so disagreeable to them, that they were willing to avoid it, at any rate whatever, either by rejecting system altogether, or by accepting a dogmatical system without reserve. The former has been their course in recent times with regard to Mineralogy; the latter was their proceeding with respect to the Linnman Botany. It is in this country alone, I believe, that Wernerian and Linnaan Societies have been instituted. Such appellations somewhat remind us of the Aristotelian and Platonic schools of ancient Greece. In the same spirit it was, that the Artificial System was at one time here considered, not as subsidiary and preparatory to the Natural Orders, but as opposed to them. This was much as if the disposition of an army in a review should be considered as inconsistent with another arrangement of it in a battle.

When Linnaus visited England in 1736, Sloans, then the patron of natural history in this country, a said to have given him a cool reception, such as was perhaps most natural from an old man to a young innovator; and Dillenius, the professor at Oxford, did not accept the sexual system. But as Pultency, the historian of English Botany, says, when his works became known, 'the simplicity of the classical characters, the uniformity of the generic notes, all confined to the parts of the fructification, and the precision which marked the specific distinctions, merits so new, soon commanded the assent of the unprejudiced.'

Perhaps the progress of the introduction of the Linnaun System into England will be best understood from the statement of T. Martyn, who was Professor of Botany in the University of Cambridge, from 1761 to 1825. 'About the year 1750,' he says, 22 'I was a pupil of the school of our great countryman Ray; but the rich vein of knowledge, the profoundness and precision, which I remarked everywhere in the Philosophia Botanica, (published in 1751,) withdrew me from my

²² Pref. to Language of Botany, 3rd edit, 1807.

pater, and I became a decided convert to that of botany which has since been generally In 1753, the Species Plantarum, which first good the specific names, made me a Linnaun kely.' In 1763, he introduced the system in tures at Cambridge, and these were the first lectures in England, Stillingfleet had already, n and Lee, in 1760, called the attention of readers to Linnaus. Sir J. Hill, (the king's ar at Kew.) in his Flora Britannica, published io, had employed the classes and generic chabut not the nomenclature, but the latter was d by Hudson, in 1762, in the Flora Anglica. young Swedes, pupils of Linnaus, Dryander lander, settled in England, and were in intimate surse with the most active naturalists, especially Bir Joseph Banks, of whom the former was an, and the latter a fellow-traveller in Cook's sted voyage. James Edward Smith was also the most zealous disciples of the Linnzan and, after the death of Linnaus, purchased rbarrums and Collections. It is related, as a proof of the high estimation in which Linwas held, that when the Swedish government of this bargain, they tried, though too late, to at these monuments of their countryman's labour lory being carried from his native land, and even o far as to send a frigate in pursuit of the ship conveyed them to England. Smith had, howthe triumph of bringing them home in safety. death they were purchased by the Linnman y. Such relics serve, as will easily be imagined, by to warm the reverence of his admirers, but strate his writings; and since they have been in country, they have been the object of the pilge of many a botanist, from every part of Europe. ave purposely confined myself to the history of innean system in the cases in which it is most applicable, omitting all consideration of more

Trapp's Transl. of Stower's Life of Linnaus, p 314.

obscure and disputed kinds of vegetables, as fems, mosses, fungi, lichens, sea-weeds, and the like. The nature and progress of a classificatory science, which it is our main purpose to bring into view, will best be understood by attending, in the first place, to the cases in which such a science has been pursued with the most decided success; and the advances which have been made in the knowledge of the more obscure vegetables, are, in fact, advances in artificial classification, only in as far as they are advances in natural classification, and in physiology.

To these subjects we now proceed.

CHAPTER V.

DGRESS TOWARDS A NATURAL SYSTEM OF BOTANY.

IVE have already said, that the formation of a Natural System of classification must result from comparison of all the resemblances and differences of things classed; but that, in acting upon this maim, the naturalist is necessarily either guided by bobscure and instinctive feeling, which is, in fact, an developed recognition of physiological relations, or be acknowledges physiology for his guide, though he obliged to assume arbitrary rules in order to interest its indications. Thus all Natural Classification of ranized beings, either begins or soon ends in Physiog; and can never advance far without the aid of at science. Still, the progress of the Natural Method botany went to such a length before it was grounded stirely on the anatomy of plants, that it will be pper, and I hope instructive, to attempt a sketch of here.

As I have already had occasion to remark, the rier systems of plants were natural; and they only need to be so, when it appeared that the problem of estructing a system admitted of a very useful solution, while the problem of devising a natural system mained insoluble. But many botanists did not so make remarks the highest object of their science. In tence, especially, a succession of extraordinary men boured at it with no inconsiderable success: and make the seconded by worthy fellow-labourers in termany and elsewhere.

The precept of taking into account all the parts of this according to their importance, may be applied cording to arbitrary rules. We may, for instance, tume that the fruit is the most important part; or may make a long list of parts, and look for agreement in the greatest possible number of these, in order construct our natural orders. The former course

was followed by Gærtner; the latter by Adanson. Gærtner's principles, deduced from the dissection of more than a thousand kinds of fruits,2 exercised, in the sequel, a great and permanent influence on the formation of natural classes. Adanson's attempt, bold and ingenious, belonged, both in time and character, to a somewhat earlier stage of the subject.3 Enthusiast.c and laborious beyond belief, but self-confident and contemptuous of the labours of others, Michael Adanson had collected, during five years spent in Senegal, an enormous mass of knowledge and materials, and had formed plans for the systems which he concerned himself thus empowered to reach, far beyond the strength and the lot of man. In his Families of Plants, however, all agree that his labours were of real value to the science. The method which he followed is thus described by his eloquent and philosophical eulogist 5

Considering each organ by itself, he formed, by pursaing its various modifications, a system of division, in which he arranged all known species according to that organ alone. Doing the same for another organ, and another, and so for many, he constructed a collection of systems of arrangement, each artificial,—each founded upon one assumed organ. The species which come together in all these systems are, of all naturally the nearest to each other; those which are separated in a few of the systems, but contiguous in the greatest number, are naturally near to each other, though less near than the former; those which are separated in a greater number, are further removed from each other in nature, and they are the more removed, the fewer are the systems in which they are

associated.

Thus, by this method, we obtain the means of estimating precisely the degree of natural affinity of all the species which our systems include, independent of ¹ De Fructibus et Seminibus Plantarum. Stuttg 1788-1791.

Cuvier's Eloge.

⁵ Cuv. Eloges, tom i. p. 284.

DOGRESS TOWARDS A NATURAL SYSTEM. 279

But the method has, Cuvier adds, the inconmore of presupposing another kind of knowledge, in though it belongs only to descriptive natural try, is no less difficult to obtain,—the knowin namely, of all species, and of all the organs of A single one neglected, may lead to relations those false, and Adanson himself, in spite of the case number of his observations, exemplifies this ince instances.

may add, that in the division of the structure egans, and in the estimation of the gradations of in each artificial system, there is still room for

mary assumption.

the mean time, the two Jussieus had presented he world a 'Natural Method,' which produced a teer impression than the 'Universal Method' of pson. The first author of the system was Bernard asieu, who applied it in the arrangement of the ca of the Trianon, in 1759, though he never pubupon it. His nephew, Autoine Laurent de ien, in his Treatise of the Arrangement of the mon,6 gave an account of the principles and orders is uncle, which he adopted when he succeeded him; at a later period, published his Genera Plantarum ndum Ordines Naturales disposita; a work, says ier, which perhaps forms as important an epoch in ciences of observation, as the Chimie of Lavoisier in the sciences of experiment. The object of the feus was to obtain a system which should be tened by the natural affinities of the plants, while, be same time, the characters by which the orders ostensibly determined, should be as clear, simple, precise, as those of the best artificial system The n points in these characters were the number of cotyledons, and the structure of the seed, and rdinate to this, the insertion of the stamina, which distinguished as epigynous, perigynous, and hypotus, according as they were inserted over, about, or

under, the germen. And the classes which were formed by the Jussieus, though they have since been modified by succeeding writers, have been so far retained by the most profound botanists, notwithstanding all the new care and new light which have been bestowed upon the subject, as to show that what was done at first, was a real and important step in the solution of the

problem.

The merit of the formation of this natural method of plants must be divided between the two Justiena It has been common to speak of the nephew, Antom Laurent, as only the publisher of his uncle's work But this appears, from a recent statement, to be highly unjust. Bernard left nothing in writing but the catalogues of the garden of the Trianon, which he had arranged according to his own views; but these catalogues consist merely of a series of names without explanation or reason added. The nephew, in 1773, undertook and executed for himself the examination of a natural family, the Ranunculacea; and he was wont to relate (as his son informs us) that it was this employment which first opened his eyes and rendered him a botanist. In the memoir which he wrote, he explained fully the relative importance of the character of plants, and the subordination of some to others;an essential consideration, which Adanson's scheme had failed to take account of. The uncle died in 1777, and his nephew, in speaking of him, compares his arrangement to the Ordines Naturales of Linnaus . Both these authors,' he says, 'have satisfied themselves with giving a catalogue of genera which approach each other in different points, without explaining the motives which induced them to place one order before another, or to arrange a genus under a certain order. These two arrangements may be conceived as problems which their authors have left for botanists to solve. Linneus published his; that of M de Jussieu is only known by the manuscript catalogues of the garden of the Trianon.'

latrod p axxv.

⁷ Prodromus Flores Penens, Ind. 8 By Adrien de Justieu, son of Orient Wight and Walker-Arnott, Antoine Laurent, in the Annales des Sc. Nat., Nov. 1834.

It was not till the younger Jussieu had employed himself for nineteen years upon botany, that he published, in 1789, his Genera Plantarum, and by this time he had so entirely formed his scheme in his head, that he began the impression without having written the book, and the manuscript was never more than

two pages in advance of the printer's type.

When this work appeared, it was not received with any enthusiasm: indeed, at that time, the revolution of states absorbed the thoughts of all Europe, and left men little leisure to attend to the revolutions of science. The author himself was drawn into the vortex of public affairs, and for some years forgot his book. The method made its way slowly and with difficulty: it was a long time before it was comprehended and adopted in France, although the botanists of that country had, a little while before, been so eager in pursuit of a natural system. In England and Germany, which had readily received the Linnaean method, its

progress was still more tardy.

There is only one point, on which it appears necessary further to dwell A main and fundamental distenction in all natural systems, is that of the Monocotyledonous and Dicotyledonous plants; that is, plants which unfold themselves from an embryo with two little leaves, or with one leaf only. This distinction produces its effects in the systems which are regulated by numbers; for the flowers and fruit of the monocotyledons are generally referrible to some law in which the number three prevails, a type which rarely occurs in dicotyledons, these affecting most commonly an arrangement founded on the number five. But it appears, when we attempt to rise towards a natural method, that this division according to the cotyledons is of a higher order than the other divisions according to number, and corresponds to a distinction in the general structure and organization of the plant. The apprehension of the due rank of this distinction has gradually grown clearer. Cuvier conceives that he finds

1 10

>9

such a division clearly marked in Lobel, in 1581, and employed by Ray as the basis of his classification a century later. This difference has had its due place assigned it in more recent systems of arrangement, but it is only later still that its full import has been distinctly brought into view. Desfontaines discovered to that the ligneous fibre is developed in an opposite manner in vegetables with one and with two cotyledons :- towards the inside in the former cust, and towards the outside in the latter; and hence these two great classes have been since termed endogenous

and exogenous.

Thus this division, according to the cotyledors, appears to have the stamp of reality put upon it, by acquiring a physiological meaning. Yet we are not allowed to forget, even at this elevated point of generalization, that no one character can be imperative in a natural method. Lamarck, who employed his great talents on botany, before he devoted himself exclusively to other branches of natural history, published his views concerning methods, systems,11 and characters. His main principle is, that no single part of a plant, however essential, can be an absolute rule for classification; and hence he blames the Jussieuian method, as giving this madmissible authority to the cotyledons. Roscoe 1- further urges that some plants, as Orchis moria, and Limodorum verecundum, have no visible cotyledous. Yet De Candolle, who laboured along with Lamarck, in the new edition of the Flore Française, has, as we have already intimated, been led, by the most careful application of the wisest principles, to a system of Natural Orders, of which Jussieu's may be looked upon as the basis; and we shall find the greatest botanists, up to the most recent period, recognizing, and employing themselves in improving, Jussieu's Natural Families; so that in the progress of

Analytique, see Dumeril, Sc. Nat.

¹² Roscoe, Linn Tr vol xi.

PROGRESS TOWARDS A NATURAL SYSTEM. 283

this part of our knowledge, vague and perplexing as it is, we have no exception to our general aphorism, that

no real acquisition in science is ever discarded.

The reception of the system of Jussieu in this country was not so ready and cordial as that of Linneus. As we have already noticed, the two systems were looked upon as rivals. Thus Roscoe, in 1810,13 endeavoured to show that Jussien's system was not more natural than the Linnean, and was inferior as an artificial system but he argues his points as if Jussieu's characters were the grounds of his distribution; which, as we have said, is to mistake the construction of a natural system. In 1803, Salisbury 14 had already assailed the machinery of the system, maintaining that there are no cases of perigynous stamens, as Jussieu assumes, but this he urges with great expressions of respect for the author of the method. And the more profound botanists of England soon showed that they could appreciate and extend the natural method, Robert Brown, who had accompanied Captain Flinders to New Holland in 1801, and who, after examining that country, brought home, in 1805, nearly four thousand species of plants, was the most distinguished example of this. In his preface to the Prodromus Florer Novæ Hollandiæ, he says, that he found himself under the necessity of employing the natural method, as the only way of avoiding serious errour, when he had to deal with so many new genera as occur in New Holland; and that he has, therefore, followed the method of Jussieu; the greater part of whose orders are truly natural, 'although their arrangement in classes, as is,' he says, 'conceded by their author, no less candid than learned, is often artificial, and, as appears to me, rests on doubtful grounds."

From what has already been said, the reader will, I trust, see what an extensive and exact knowledge of the vegetable world, and what comprehensive views of affinity, must be requisite in a person who has to modify the natural system so as to make it suited to

⁴³ Linn, Tr vol xl, p. 50.

receive and arrange a great number of new plants, extremely different from the genera on which the arrangement was first formed, as the New Holland genera for the most part were. He will also see how impossible it must be to convey by extract or description any notion of the nature of these modifications it is enough to say, that they have excited the applause of botanists wherever the science is studied, and that they have induced M. de Humboldt and his fellowlabourers, themselves botanists of the first rank, to dedicate one of their works to him in terms of the strongest admiration. 16 Mr. Brown has also published special disquisitions on parts of the Natural System; as on Jussieu's Protencea; .6 on the Asclepindea, & natural family of plants which must be separated from Jussieu's Apocynea: 17 and other similar labours.

We have, I think, been led, by our survey of the history of Botany, to this point; - that a Natural Method directs us to the study of Physiology, as the only means by which we can reach the object. This conviction, which in botany comes at the end of & long series of attempts at classification, offers itself at once in the natural history of animals, where the physiological signification of the resemblances and differences is so much more obvious. I shall not, therefore, consider any of these branches of natural history in detail as examples of mere classification. They will come before us, if at all, more properly when we consider the classifications which depend on the functions of organs, and on the corresponding modifications which they necessarily undergo, that is, when we trace the results of Physiology. But before we proceed to sketch the history of that part of our knowledge, there are a few points in the progress of Zoology, understood as a mere classificatory science, which appear to me sufficiently instructive to make it worth our while to dwell upon them.

ROGRESS TOWARDS A NATURAL SYSTEM. 285

and Ed.] [Mr. Lindley's recent work, The Vegetable ndom, (1846,) may be looked upon as containing the view of the recent history of Systematic Botany. he Introduction to this work, Mr. Lindley has given count of various recent works on the subject; as rdh's Classes Plantarum (1826); Perleb's Lehrbuch Naturgeschichte der Pflanzenreich (1826); Dumor-Florula Belgica (1827); Bartling's Ordines Natu-Plantarum (1830); Hess's Uchernicht der Phagenischen Naturlichen Pflanzenfamilien (1832); niz's Naturliches System des Pflanzenreich's (1832); minow's Prime Linea Systematis Natura (1834); Corpus Florarum provincialium Sueciæ (1835); tins's Conspectus Regni Vegetabilis secundum Chatores Morphologicos (1835); Sir Edward F. Brom-As System, as published in the Edinburgh Journal tother Journals (1836-1840); Endlicher's Genera starum secundum Ordines Naturales disposita (1836-(o): Perleb's Clavis Classicum Ordinum et Famimm (1838); Adolphe Brongniart's Enumération Genres de Plantes (1843); Meisner's Plantarum adarrum Genera secundum Ordines Naturales digesta (43); Horaninow's Tetractys Natura, seu Systema nquemembre omnium Naturalium (1843); Adrien Jussieu's Cours Elémentaire d'Histoire Naturelle: mique (1844).

ongly the superior value of natural as compared the artificial systems; his principles being, I think, and such as I have attempted to establish in the slosophy of the Sciences, Book viii., Chapter ii. He test that the leading idea which has been kept in view the compilation of his work is this maxim of Fries; ingula sphera (sectio) ideam quandam exponit, inque ejus character notione simplici optime expritur; and he is hence led to think that the true chatters of all natural assemblages are extremely simple. One of the leading features in Mr. Lindley's system that he has thrown the Natural Orders into groups bordinate to the higher divisions of Classes and ch-classes. He had already attempted this, in imita-

tion of Agardh and Bartling, in his Nixue Plantarum. (1833.) The groups of Natural Orders were there called Ninus (tendencies); and they were denoted by names ending in ales. but these groups were further subordinated to Cohorts. Thus the first member of the arrangement was Class I. Exogenæ. Sub-class I. POLYPETALE. Cohort I. ALBUMINOSÆ Ranales. Natural Orders included in this Nirus, Ranunculacese, Saracenicese, Papaveracese, &c. In the Vegetable Kingdom, the groups of Natural Orders are termed Alliances. In this work, the Sub-classes of the Exogens are four: I. DicLinous; II. Hypogynous; III. PERIGYNOUS, IV. EPIGYNOUS; and the Alliances are subordinated to these without the intervention of Cohorts.

Mr. Lindley has also, in this as in other works, given English names for the Natural Orders. Thus for Nymphacea, Ranunculacea, Tamaricacea, Zygophyllacea, Eleatrinacea, he substitutes Water Lilies, Crowfoots, Tamarisks, Bean-Capers, and Water-Peppers; for Malvacea, Aurantiacea, Gentianacea, Primulacea, Urtiacea, Euphorbiacea, he employs Mallow-worts, Citron-worts, Gentian-worts, Primworts, Nettle-worts, Spurge-worts; and the terms Orchids, Hippurids, Amaryllida, Irids, Typhads, Arads, Cucurbits, are taken as English equivalents for Orchidacea, Haloragarea, Amaryllidacea, Irulacea, Typhacea, Aracea, Cucurbitacea. All persons who wish success to the study of botany in England must rejoice to see it tend to assume this idiomatic shape.]

CHAPTER VI.

THE PROGRESS OF SYSTEMATIC ZOOLOGY.

THE history of Systematic Botany, as we have presented it, may be considered as a sufficient type of the general order of progression in the sciences of classification. It has appeared, in the survey which we have had to give, that this science, no less than those which we first considered, has been formed by a series of inductive processes, and has, in its history, Epochs at which, by such processes, decided advances were made. The important step in such cases is, the seizing upon some artificial mark which conforms to natural resemblances;—some basis of arrangement and nomenclature by means of which true propositions of considerable generality can be enunciated. The advance of other classificatory sciences, as well as botany, must consist of such steps, and their course, like that of botany, must (if we attend only to the real additions made to knowledge,) be gradual and progressive, from the earliest times to the present.

To exemplify this continued and constant progression in the whole range of Zoology, would require vast knowledge and great labour; and is, perhaps, the less necessary, after we have dwelt so long on the history of Botany, considered in the same point of view. But there are a few observations respecting Zoology in general which we are led to make in consequence of statements recently promulgated; for these statements seem to represent the history of Zoology as having followed a course very different from that which we have just ascribed to the classificatory sciences in general. It is held by some naturalists, that not only the formation of a systematic classification in Zoology dates as far back as Aristotle; but that his classification is, in many respects, superior to some of the most admired and recent attempts of modern

times.

If this were really the case, it would show that at least the idea of a Systematic Classification had been formed and developed long previous to the period to which we have assigned such a step, and it would be difficult to reconcile such an early maturity of Zoology with the conviction, which we have had impressed upon us by the other parts of our history, that not only labour but time, not only one man of genius but several, and those succeeding each other, are requisite to the formation of any considerable science.

But, in reality, the statements to which we refer, respecting the scientific character of Aristotle's Zoological system, are altogether without foundation, and this science confirms the lessons taught us by all the others. The misstatements respecting Aristotle's doctrines are on this account so important, and are so curious in themselves, that I must dwell upon them a

little.

Aristotle's nine Books On Animals are a work enumerating the differences of animals in almost all conceivable respects, -in the organs of sense, of motion, of nutrition, the interior anatomy, the exterior covering, the manner of life, growth, generation, and many other circumstances. These differences are very philosophically estimated. 'The corresponding parts of animals,' he says,1 ' besides the differences of quality and circumstance, differ in being more or fewer, greater or smaller, and, speaking generally, in excess and defect. Thus some animals have crustaceous coverings. others hard shells; some have long beaks, some short; some have many wings, some have few. Some again have parts which others want, as crests and spurs." He then makes the following important remark: 'Some animals have parts which correspond to those of others, not as being the same in species, nor by excess and defect, but by analogy; thus a claw is analogous to a thorn, and a nail to a hoof, and a hand to the nipper of a lobster, and a feather to a scale; for what a feather is in a bird, that is a scale in a fish."

i Lib i c i.

It will not, however, be necessary, in order to understand Aristotle for our present purpose, that we should discuss his notion of Analogy. He proceeds to state his object, which is, as we have said, to describe the differences of animals in their structure and habits. He then observes, that for structure, we may take Man for our type, as being best known to us; and the remainder of the first Book is occupied with a description of man's body, beginning from the head, and proceeding to the extremities.

In the next Book, (from which are taken the principal passages in which his modern commentators detect his system,) he proceeds to compare the differences of parts in different animals, according to the order which he had observed in man. In the first chapter he speaks of the head and neck of animals; in the second, of the parts analogous to arms and hands; in the third, of the breast and paps, and so on, and thus he comes, in the seventh chapter, to the legs, feet, and toes; and in the eleventh, to the teeth, and

so to other parts.

The construction of a classification consists in the selection of certain parts, as those which shall eminently and peculiarly determine the place of each species in our arrangement. It is clear, therefore, that such an enumeration of differences as we have described, supposing it complete, contains the materials of all possible classifications. But we can with no more propriety say that the author of such an enumeration of differences is the author of any classification which can be made by means of them, than we can say that a man who writes down the whole alphabet writes down the solution of a given riddle or the answer to a particular question.

Yet it is on no other ground than this enumeration, so far as I can discover, that Aristotle's 'System' has been so decidedly spoken of, and exhibited in the most formal tabular shape. The authors of this Systema Aristotelicum, have selected, I presume, the fol-

² Lib f. e if. 2 c. iil. 4 Linnaan Transactions, vol. Xvl. p. 24.
VOL. 11L U

lowing passages from the work On Animals, as they might have selected any other; and by arranging them according to a subordination unknown to Aristotle himself, have made for him a scheme which undoubtedly hears a great resemblance to the most complete systems of modern times.

Book I., chap. v.— Some animals are viviparous, some oviparous, some vermiparous. The viviparous are such as man, and the horse, and all those animals which have hair, and of aquatic animals, the whale

kind, as the dolphin and cartilagmous fishes.'

Book II., chap. vii.— Of quadrupeds which have blood and are viviparous, some are (as to their extremities,) many-cloven, as the hands and feet of man. For some are many-toed, as the lion, the dog, the panther; some are bifid, and have hoofs instead of nails, as the sheep, the goat, the elephant, the hippopotamus; and some have undivided feet, as the sold-hoofed animals, the horse and ass. The swine kind share both characters.'

Chap. ii.—'Animals have also great differences in the teeth, both when compared with each other and with man. For all quadrupeds which have blood and are viviparous, have teeth. And in the first place, some are ambidental, (having teeth in both jaws:) and some are not so, wanting the front teeth in the upper jaw. Some have neither front teeth nor horns, as the camel; some have tusks, as the boar, some have not. Some have serrated teeth, as the lion, the panther, the dog; some have the teeth unvaried, as the horse and the ox; for the animals which vary their cutting teeth have all serrated teeth. No animal has both tusks and horns; nor has any animal with serrated teeth either of those weapons. The greater part have the front teeth cutting, and those within broad.'

These passages undoubtedly contain most of the differences on which the asserted Aristotelian classification rests; but the classification is formed by using

^{6 &#}x27;Αμφάζοντα.

ο Χαυλιόδοντα.

a. ⁷ Kapyapódorra.

⁸ 'Ανεπάλλακτα.

theracters drawn from the teeth, in order to subis those taken from the feet; whereas in Aristotle
two sets of characters stand side by side, along
dozens of others; any selection of which, emid according to any arbitrary method of subortion, might with equal justice be called Aristotle's

Ay, for instance, in order to form subdivisions of als, should we not go on with Aristotle's contion of the second of the above-quoted passages, ad of capriciously leaping to the third? 'Of these have horns, some have none . . . Some have a k-joint, some have none . . . Of those which horns, some have them solid throughout, as the others, for the most part, hollow . . . Some cast horns, some do not.' If it be replied, that we not, by means of such characters, form a tenable gical system; we again ask by what right we me Aristotle to have made or attempted a systic arrangement, when what he has written, taken in natural order, does not admit of being condition a system.

main, what is the object of any classification? at least, among others. To enable the person uses it to study and describe more conveniently bjects thus classified. If, therefore, Aristotle had ed or adopted any system of arrangement, we Id see it in the order of the subjects in his work. rdingly, so far as he has a system, he professes to this use of it. At the beginning of the fifth where he is proceeding to treat of the different of generation of animals, he says, 'As we cerly made a Division of animals according to kinds, we must now, in the same manner, give a rel survey of their History (θεωρίαν). Except, ed, that in the former case we made our comcoment by a description of man, but in the present nce we must speak of him last, because he requires

^{* &#}x27;Αστράγαλον.

most study. We must begin then with those animals which have shells: we must go on to those which have softer coverings, as crustacea, soft animals, and insects; after these, fishes, both viviparous and overarous, then birds; then land animals, both viviparous

and oviparous.'

It is clear from this passage that Aristotle had certain wide and indefinite views of classification, which though not very exact, are still highly creditable to him, but it is equally clear that he was quite unconscious of the classification that has been ascribed to him. If he had adopted that or any other system, this was precisely the place in which he must have

referred to and employed it.

The honour due to the stupendous accumulation of zoological knowledge which Aristotle's works contain, cannot be tarnished by our denying him the credit of a system which he never dreamt of, and which, from the nature of the progress of science, could not possibly be constructed at that period. But, in reality, we may exchange the mistaken claims which we have been contesting for a better, because a truer praise. Aristotle does show, as far as could be done at his time, a perception of the need of groups, and of names of groups, in the study of the animal kingdom; and thus may justly be held up as the great figure in the Prelude to the Formation of Systems which took place in more advanced scientific times.

This appears, in some measure, from the passage last quoted. For not only is there, in that, a clear recognition of the value and object of a method in natural history; but the general arrangement of the animal kingdom there proposed has considerable scientific ment, and is, for the time, very philosophical. But there are passages in his work in which he shows a wish to carry the principle of arrangement more into detail. Thus, in the first Book, before proceeding to his survey of the differences of animals, lo after speaking of such

as Quadrupeds, Birds, Fishes, Cetaceous, Testa-Crustaceous Animals, Mollusks, Insects, he says, p. vu.)

Animals cannot be divided into large genera, in the one kind includes many kinds. For some kinds unique, and have no difference of species, as man. In have such kinds, but have no names for them. It all quadrupeds which have not wings, have blood, of these, some are viviparous, some oviparous, which are viviparous have not all hair; those in the are oviparous have scales. We have here a festly intentional subordination of characters: In kind of regret that we have not names for the case here indicated, such, for instance, as viviparous trapeds having hair. But he follows the subject further detail. Of the class of viviparous qualeds, he continues, there are many genera, 11 but

as man, lion, stag, horse, dog, and the like. Yet is a genus of animals that have names, as the names, the oreus, the ginnus, the innus, and inimal which in Syria is called heminus (mule); these are called mules from their resemblance only; being mules, for they breed of their own kind, excepte, he adds, that is, because we do not possess unized genera and generic names of this kind, 'we

take the species separately, and study the nature

hese passages afford us sufficient ground for placing totle at the head of those naturalists to whom the views of the necessity of a zoological system are It was, however, very long before any worthy major appeared, for no additional step was made modern times. When Natural History again came studied in Nature, the business of classification, was pursued with interest in animals, as in plants.

The steps of its advance were similar in the two cases; -by successive naturalists, various systems of artificial marks were selected with a view to precision and convenience; - and these artificial systems assumed the existence of certain natural groups, and of a natural system to which they gradually tended. But there was this difference between botany and zoology:the reference to physiological principles, which, as we have remarked, influenced the natural systems of vegetables in a latent and obscure manner, botanists being guided by its light, but hardly aware that they were so, affected the study of systematic zoology more directly and evidently. For men can neither overlook the general physiological features of animals, nor avoid being swayed by them in their judgments of the affinities of different species. Thus the classification of zoology tended more and more to a union with comparative anatomy, as the science was more and more improved.12 But comparative anatomy belongs to the subject of the next Book; and anything it may be proper to say respecting its influence upon zoological arrangements, will properly find a place there.

It will appear, and indeed it hardly requires to be proved, that those steps in systematic zoology which are due to the light thrown upon the subject by physiology, are the result of a long series of labours by various naturalists, and have been, like other advances in science, led to and produced by the general progress of such knowledge. We can hardly expect that the classificatory sciences can undergo any material improvement which is not of this kind. Very recently, however, some authors have attempted to introduce into these sciences certain principles which do not, at first sight, appear as a continuation and extension of the previous researches of comparative anatomists. I speak, in particular, of the doctrines of a Circular Progression in the series of affinity, of a Quinary Division

¹⁹ Cavier, Leg. & Anat. Comp. vol. i. p. 17.

such circular groups; and of a relation of Analogy

m the relation of Affinity.

The doctrine of Circular Progression has been proanded principally by Mr. Macleay; although, as he shown, is there are suggestions of the same kind to found in other writers. So far as this view negathe doctrine of a mere linear progression in ture, which would place each genus in contact only the preceding and succeeding ones, and so far as requires us to attend to more varied and ramified memblances, there can be no doubt that it is supported the result of all the attempts to form natural sys-But whether that assemblage of circles of rangement which is now offered to naturalists, be true and only way of exhibiting the natural relams of organized bodies, is a much more difficult estion, and one which I shall not here attempt to mine; although it will be found, I think, that those lalogies of science which we have had to study, would fail to throw some light upon such an inquiry. he prevalence of an invariable numerical law in the risions of natural groups, (as the number five is parted to prevail by Mr. Macleay, the number ten by ies, and other numbers by other writers,) would be serious fact, if established; but it is easy to see that thing short of the most consummate knowledge of staral history, joined with extreme clearness of view al calmness of judgment, could enable any one to conounce on the attempts which have been made to blish such a principle. But the doctrine of a relaon of Analogy distinct from Affinity, in the manner hich has recently been taught, seems to be obviously variance with that gradual approximation of the insificatory to the physiological sciences, which has speared to us to be the general tendency of real nowledge. It seems difficult to understand how a dirence to such relations as those which are offered

¹³ Linn. Trans. vol avi. p. 9.

as examples of analogy, 14 can be otherwise than a retrograde step in science.

Without, however, now dwelling upon these points, I will treat a little more in detail of one of the branches

of Zoology.

[2nd Ed.] [For the more recent progress of Systematic Zoology, see in the Reports of the British Association, in 1834, Mr. L. Jenyns's Report on the Recent Progress and Present State of Zoology, and in 1844, Mr. Strickland's Report on the Recent Progress and Present State of Ornsthology. In these Reports, the questions of the Circular Arrangement, the Quinary System, and the relation of Analogy and Affinity are discussed.]

CHAPTER VII.

THE PROGRESS OF ICETHYOLOGY.

F it had been already observed and admitted that L sciences of the same kind follow, and must follow, the same course in the order of their developement, it would be unnecessary to give a history of any special branch of Systematic Zoology; since botany has already afforded us a sufficient example of the progress of the classificatory sciences. But we may be excused for introducing a sketch of the advance of one department of zoology, since we are led to the attempt by the peculiar advantage we possess in having a complete history of the subject written with great care, and brought up to the present time, by a naturalist of unequalled talents and knowledge. I speak of Cuvier's Historical View of Ichthyology, which forms the first chapter of his great work on that part of natural history. The place and office in the progress of this science, which is assigned to each person by Cuvier, will probably not be lightly contested. It will, therefore, be no small confirmation of the justice of the views on which the distribution of the events in the history of botany was founded, if Cuvier's representation of the history of ichthyology offers to us obviously a distribution almost identical.

We shall find that this is so;—that we have, in soology as in botany, a period of unsystematic knowledge; a period of misapplied erudition; an epoch of the discovery of fixed characters; a period in which many systems were put forwards; a struggle of an artificial and a natural method; and a gradual tendency of the natural method to a manifestly physiological character. A few references to Cuvier's history will enable us to illustrate these and other analogies.

Period of Unsystematic Knowledge. —It would be easy to collect a number of the fabulous stories of early times, which formed a portion of the imaginary knowledge of men concerning animals as well as plants.

But passing over these, we come to a long period and a great collection of writers, who, in various ways, and with various degrees of merit, contributed to augment the knowledge which existed concerning fish, while as yet there was hardly ever any attempt at a classification of that province of the animal kingdom. Among these writers, Aristotle is by far the most important Indeed he carried on his zoological researches under advantages which rarely fall to the lot of the naturalist; if it be true, as Athenaus and Pliny state, that Alexander gave him sums which amounted to nine hundred talents, to enable him to collect materials for his history of animals, and put at his disposal several thousands of men to be employed in hunting. fishing, and procuring information for him. works of his on Natural History which remain to us are, nine Books Of the History of Animals, four, On the Parts of Animals; five, On the Generation of Animals, one, On the Going of Animals; one, Of the Sensatums, and the Organs of them; one, On Sleeping and Waking; one, On the Motion of Animals; one, On the Length and Shortness of Life; one, On Youth and Old Age; one, On Life and Death; one, On Respiration. The knowledge of the external and internal conformation of animals, their habits, instancts, and uses, which Aristotle displays in these works, is spoken of as something wonderful even to the naturalists of our own time. And he may be taken as a sufficient representative of the whole of the period of which we speak; for he is, says Cuvier,2 not only the first, but the only one of the ancients who has treated of the natural history of fisher (the province to which we now confine ourselves.) in a scientific point of view, and in a way which shows genius

We may pass over, therefore, the other ancient authors from whose writings Cuvier, with great learning and sagacity, has levied contributions to the history of ichthyology; as Theophrastus, Ovid, Pliny, Oppian, Atheneus, Ælian, Ausonius, Galen. We may, too, leave unnoticed the compilers of the middle ages,

¹ Cuv. Hist. Nat. des Polssons, 1, 13.

did little but abstract and disfigure the portions stural history which they found in the ancienta. hyological, like other knowledge, was scarcely be except in books, and on that very account was inderstood when it was found.

riod of Erudition.—Better times at length came, men began to observe nature for themselves. The great authors who are held to be the founders todern ichthyology, appeared in the middle of the anth century; these were Bélon, Rondelet, and ini, who all published about 1555. very different from the compilers who filled the ral from Aristotle to them, themselves saw and mined the fishes which they describe, and have faithful representations of them. But, resembling est respect the founders of modern botany, Bras-Ruellius, Tragus, and others, they resembled in this also, that they attempted to make their observations a commentary upon the ancient Faithful to the spirit of their time, they are nore careful to make out the names which each bore in the ancient world, and to bring together of their history from the authors in whom names occur, than to describe them in a lucid mer; so that without their figures, says Cuvier, it d be almost as difficult to discover their species as of the ancients.

they can be recognized, is little appreciated at although it is in reality the main-spring of the ress of the sciences of classification. Aristotle dreamt that the nomenclature which was in use time could ever become obscure; hence he has a no precaution to enable his readers to recognize species of which he speaks; and in him and in ancient authors, it requires much labour and felicity of divination to determine what the mean. The perception of this difficulty among maturalists led to systems, and to nomenclature

³ Cavier, p. 17.

founded upon system; but these did not come into being immediately at the time of which we speak; nor till the evil had grown to a more inconvenient

magnitude.

Period of Accumulation of Materials. Exotic Collections.—The fishes of Europe were for some time the principal objects of study; but those of distant regions soon came into notice.4 In the seventeenth century the Dutch conquered Brazil, and George Margrave, employed by them, described the natural productions of the country, and especially the fishes. Bontms, in like manner, described some of those of Batavia. Thus these writers correspond to Rumphius and Rheeds in the history of botany. Many others might be meationed; but we must hasten to the formation of systems.

which is our main object of attention.

Epoch of the Fixation of Characters. Ray and Willoughby. In botany, as we have seen, though Ray was one of the first who invented a connected system, he was preceded at a considerable interval by Casalpinus, who had given a genuine solution of the same problem. It is not difficult to assign reasons why a sound classification should be discovered for plants at an earlier period than for fishes. The vastly greater number of the known species, and the facilities which belong to the study of vegetables, give the botanist great advantage, and there are numerical relations of a most definite kind, (for instance, the number of parts of the seed vessel employed by Cæsalpinus as one of the bases of his system,) which are tolerably obvious in plants, but which are not easily discovered in animals. And thus we find that in ichthyology, Ray, with his pupil and friend Willoughby, appears as the first founder of a tenable system.

The first great division in this system is into cartilaginous and bony fishes; a primary division, which

recognovit, coaptavit, supplevit Francisci Willoughbell, Armi- librum etiam primum et secungeri, de Historia Piscium, libri iv. dum adjecit Joh, Rains. Oxfords

⁴ Cuy p. 43.

Jusan et sura pillous Sucietatis Regim 1668. Londinensis ed.ti, &c. Totum opus

in his latest labours. The subdivisions are fined by the general form of the fish, (as long or the teeth, the presence or absence of ventral number of dorsal tins, and the nature of the of the fins, as soft or prickly. Most of these ters have preserved their importance in later s; especially the last, which, under the terms pterygian and acanthopterygian, holds a place in trecent arrangements.

this system was a true first approximation to ion of the problem, appears to be allowed by lists. Although, says Cuvier, there are in it no well defined and well limited, still in many the species are brought together very naturally, such a way that a few words of explanation ruffice to form, from the groups thus presented ceveral of the genera which have since been extracted in botany, as we have seen, general ardly maintained with any degree of precision, binary nomenclature of Linnaus made this a matter of such immense convenience.

amount of this convenience, the value of a and sure nomenclature, had not yet been duly ted. The work of Willoughby forms an epoch, happy epoch, in the history of ichthyology; for ience, once systematized, could distinguish the om the old, arrange methodically, describe clearly, is a Willoughby had no nomenclature of his and no fixed names for his genera, his immediate the was not great. I will not attempt to trace affuence in succeeding authors, but proceed to at important step in the progress of system.

countryman and intimate friend of Linnaus; mdered to ichthyology nearly the same services Linnaus rendered to botany. In his Philo-Lehthyologica, he analysed all the interior and preparts of animals, he created a precise termi-

nology for the different forms of which these parts are susceptible; he laid down rules for the nomenclature of genera and species; besides his improvements of the subdivision of the class. It is impossible not to be struck with the close resemblance between these stem, and those which are due to the Fundamenta Botanics. The latter work appeared in 1736, the former was published by Linneus, after the death of the author, in 1738, but Linnæus had already, as early as 1735, made use of Artedi's manuscripts in the ichthyological part of his Systema Nature. We cannot doubt that the two young naturalists, (they were nearly of the same age,) must have had a great influence upon each other's views and labours; and it would be difficult now to ascertain what portion of the peculiar ments of the Linnean reform was derived from Artedi. But we may remark that, in ichthyology at least, Artedi appears to have been a naturalist of more original views and profounder philosophy than his friend and editor, who afterwards himself took up the subject. The reforms of Linnaus, in all parts of natural history, appear as if they were mainly dictated by a love of elegance, symmetry, clearness, and definiteness; but the improvement of the ichthyological system by Artedi seems to have been a step in the progress to a natural arrangement. His genera, which are fortyfive in number, are so well constituted, that they have almost all been preserved; and the subdivisions which the constantly-increasing number of species has compelled his successors to introduce, have very rarely been such that they have led to the transposition of his genera.

In its bases, however, Artedi's was an artificial system. His characters were positive and decisive, founded in general upon the number of rays of the membrane of the gills, of which he was the first to mark the importance;—upon the relative position of the fins, upon their number, upon the part of the mouth where the teeth are found, upon the conforma-

⁹ Cavier, p. 71.

an of the scales. Yet, in some cases, he has recourse the interior anatomy.

Linnaus himself at first did not venture to deviate em the footsteps of a friend, who, in this science, had in his master. But in 1758, in the tenth edition of Systema Natura, he chose to depend upon himself, d devised a new ichthyological method. He divided me genera, united others, gave to the species trivial mes and characteristic phrases, and added many mies to those of Artedi. Yet his innovations are the most part disapproved of by Cuvier; as his spaferring the chondropterygian fishes of Artedi to class of reptiles, under the title of Amphibia ntes, and his rejecting the distinction of acanthoptegian and malacopterygian, which, as we have seen, prevailed from the time of Willoughby, and introaming in its stead a distribution founded on the mence or absence of the ventral fins, and on their mation with regard to the pectoral fins. 'Nothing,' Cuvier, 'more breaks the true connexions of nern than these orders of apodes, jugulares, thoracici, d abdominales.

Thus Linnaus, though acknowledging the value and portance of natural orders, was not happy in his tempts to construct a system which should lead to In his detection of good characters for an dificial system he was more fortunate. He was ways attentive to number, as a character; and he the very great merit 10 of introducing into the resification the number of rays of the fins of each secies This mark is one of great importance and use. and this, as well as other branches of natural history, rived incalculable advantages from the more general poits of the illustrious Swede, 11—the precision of is characters, the convenience of a well-settled termiclogy, the facility afforded by the binary nomenclature. here recommendations gave him a pre-eminence which acknowledged by almost all the naturalists of his me, and displayed by the almost universal adoption

¹⁰ Covier, p. 74.

of his nomenclature, in zoology, as well as in botan; and by the almost exclusive employment of his distributions of classes, however imperfect and artificial they

might be.

And even 12 if Linneus had had no other merit than the impulse he gave to the pursuit of natural science, this alone would suffice to immortalize his name. In rendering natural history easy, or at least in making it appear so, he diffused a general taste for it. The great took it up with interest; the young, full of ardour, rushed forwards in all directions, with the sole intention of completing his system. The civilized world was eager to build the edifice which Linneus

had planned.

This spirit, among other results, produced voyages of natural historical research, sent forth by nations and sovereigns. George the Third of England had the honour of setting the example in this noble career, by sending out the expeditions of Byron, Wallis, and Carteret, in 1765. These were followed by those of Bougainville, Cook, Forster, and others. Russia also scattered several scientific expeditions through her vast dominions; and pupils of Linnaeus sought the my shores of Greenland and Iceland, in order to apply his nomenclature to the productions of those climes. But we need not attempt to convey any idea of the vast stores of natural historical treasures which were thus collected from every part of the globe.

I shall not endeavour to follow Cuvier in giving an account of the great works of natural history to which this accumulation of materials gave rise; such as the magnificent work of Bloch on Fishes, which appeared in 1782—1785: nor need I attempt, by his assistance, to characterize or place in their due position the soveral systems of classification proposed about this time. But in the course of these various essays, the distinction of the artificial and natural methods of classification came more clearly into view than before, and this is a point so important to the philosophy of the subject,

that we must devote a few words to it.

¹² Cuvier, p 88

Separation of the Artificial and Natural Methods in Achthyology.—It has already been said that all socalled artificial methods of classification must be natural, at least as to the narrowest members of the system: thus the artificial Linnean method is natural as to species, and even as to genera. And on the other hand, all proposed natural methods, so long as they remain unmodified, are artificial as to their characteristic marks. Thus a Natural Method is an attempt to provide positive and distinct characters for the wider as well as for the narrower natural groups. These considerations are applicable to zoology as well as to botany. But the question, how we know natural groups before we find marks for them, was, in botany, as we have seen, susceptible only of vague and obscure answers: -the mind forms them, it was said, by taking the aggregate of all the characters; or by establishing subordination of characters. And each of these answers had its difficulty, of which the solution appeared to be, that in attempting to form natural orders we are really guided by a latent undeveloped estimate of physiological relations. Now this principle, which was so dimly seen in the study of vegetables, shines out with much greater clearness when we come to the study of animals, in which the physiological relations of the parts are so manifest that they cannot be overlooked, and have so strong an attraction for our curiosity that we cannot help having our judgments influenced by them. Hence the superiority of natural systems in zoology would probably be far more generally allowed than in botany; and no arrangement of animals which, in a large number of instances, violated strong and clear natural affinities, would be tolerated because it answered the purpose of enabling us easily to find the name and place of the animal in the artificial system. Every system of zoological arrangement may be supposed to aspire to be a natural system. But according to the various habits of the minds of systematizers, this object was pursued more or less steadily and successfully; and these differences came more and

more into view with the increase of knowledge and the

multiplication of attempts.

Bloch, whose ichthyological labours have been mentioned, followed in his great work the method of Linnaus. But towards the end of his life he had prepared a general system, founded upon one single numerical principle,—the number of fins; just as the sexual system of Linnaus is founded upon the number of stamina: and he made his subdivisions according to the position of the ventral and pectoral fins; the same character which Linnaus had employed for his primary division. He could not have done better, says Cuvier, if his object had been to turn into ridicule all artificial methods, and to show to what absurd combinations they may lead.

Cuvier himself, who always pursued natural systems with a singularly wise and sagacious consistency, attempted to improve the ichthyological arrangements which had been proposed before him. In his Regns Animal, published in 1817, he attempts the problem of arranging this class; and the views suggested to him, both by his successes, and his failures, are so mestructive and philosophical, that I cannot illustrate the

subject better than by citing some of them.

'The class of fishes,' he says, 14 'is, of all, that which offers the greatest difficulties, when we wish to subdivide it into orders, according to fixed and obvious characters. After many trials. I have determined on the following distribution, which in some instances is wanting in precision, but which possesses the advantage of keeping the natural families entire.

Fish form two distinct series,—that of chendropterugians or cartilaginous fish, and that of fish properly

so called.

The first of these series has for its character, that the palatine bones replace, in it, the bones of the upper jaw: moreover the whole of its structure has evident analogies, which we shall explain.

' It divides itself into three ORDERS:

¹⁸ p. 108.

The Cyclostomes, in which the jaws are soldered pudiced into an immoveable ring, and the bronchise open in numerous holes.

The SELACIANS, which have the bronchise like the

receding, but not the jaws.

The STURONIANS, in which the bronchize are open

usual by a slit furnished with an operculum.

The second series, or that of ordinary fishes, offers in the first place, a primary division, into those of thich the maxillary bone and the palatine arch are overailed (engrenés) to the skull. Of these I make a order of Pectoenaths, divided into two families; be aumnodonts and the scleroderms.

After these I have the fishes with complete jaws, at with bronchise which, instead of having the form f combs, as in all the others, have the form of a series little tufts (houppes). Of these I again form an order, which I call LOPHOBRANCHS, which only includes

me family.

There then remains an innumerable quantity of takes, to which we can no longer apply any characters accept those of the exterior organs of motion. After long examination, I have found that the least bad of these characters is, after all, that employed by Ray and Artedi, taken from the nature of the first rays of the dorsal and of the anal fin. Thus ordinary fishes are divided into Malacopterygians, of which all the pays are soft, except sometimes the first of the dorsal in or the pectorals,—and Acanthopterygians, which have always the first portion of the dorsal, or of the first dorsal when there are two, supported by spinous mys, and in which the anal has also some such rays, and the ventrals, at least, each one.

The former may be subdivided without inconvenience, according to their ventral fins, which are cometimes situate behind the abdomen, sometimes adherent to the apparatus of the shoulder, or, finally,

are sometimes wanting altogether.

We thus arrive at the three orders of ABDOMINAL MALACOPTERYGIANS, of SUBBRACHIANS, and of APODES; sech of which includes some natural families which

we shall explain: the first, especially, is very parmerous.

But this basis of division is absolutely impracticable with the Acanthopterygians; and the problem of establishing among these any other subdivision than that of the natural families has hitherto remained for mainsoluble. Fortunately several of these families after characters almost as precise as those which we could give to true orders.

'In truth, we cannot assign to the families of fishes, ranks as marked, as for example, to those of mammifers. Thus the Chondropterygians on the one hard hold to reptiles by the organs of the senses, and by those of generation in some, and they are related to mollusks and worms by the imperfection of the skeleton in others.

'As to Ordinary Fishes, if any part of the organization is found more developed in some than in others, there does not result from this any pre-eminence sufficiently marked, or of sufficient influence upon their whole system, to oblige us to consult it in the methodical arrangement.

'We shall place them, therefore, nearly in the order in which we have just explained their characters.'

I have extracted the whole of this passage, because, though it is too technical to be understood in detail by the general reader, those who have followed with any interest the history of the attempts at a natural classification in any department in nature, will see here a fine example of the problems which such attempts propose, of the difficulties which it may present, and of the reasonings, labours, cautions, and varied resources, by means of which its solution is sought, when a great philosophical naturalist girds himself to the task. We see here, most instructively. how different the endeavour to frame such a natural system, is from the procedure of an artificial system, which carries imperatively through the whole of a class of organized beings, a system of marks either arbitrary, or conformable to natural affinities in a partial degree. And we have not often the advantage and fully indicated, as is done here, and in the

tions of the separate orders.

arrangement Cuvier adhered to in all its main both in the second edition of the Regne Animal, ed in 1821, and in his Histoire Naturelle des s, of which the first volume was published in but which unfortunately was not completed at of his death. It may be supposed, therefore, accordance with those views of zoological phy, which it was the business of his life to nd to apply, and in a work like the present, spon so large a question of natural history, we directed in a great measure by the analogy of story of science, and by the judgments which bost to have the character of wisdom, we appear estified in taking Cuvier's ichthyological system mearest approach which has yet been made to a method in that department.

true natural method is only one: artificial and even good ones, there may be many, as seen in botany; and each of these may have santages for some particular use. On some is of this kind, on which naturalists themselves ardly yet had time to form a stable and distinct it is not our office to decide. But judging, as laready said, from the general analogy of the sciences, I find it difficult to conceive that the logical method of M. Agassiz, recently prowith an especial reference to fossil fishes, can prwise than an artificial method. It is founded on one part of the animal, its scaly covering, un on a single scale. It does not conform to ich almost all systematic ichthyologists hitherto maidered as a permanent natural distinction of order;—the distinction of bony and cartilafishes; for it is stated that each order contains es of both. 15 I do not know what general ical or physiological truths it brings into view;

Dr. Buckland's Bridgewoter Treatise, p. 170.

but they ought to be very important and striking ones, to entitle them to supersede those which led Cuvier to his system. To this I may add, that the new ichthyological classification does not seem to form, as we should expect that any great advance towards a natural system would form, a connected sequel to the past history of ichthyology;—a step to which antener discoveries and improvements have led, and in which

they are retained.

But notwithstanding these considerations, the method of M. Agassiz has probably very great advantages for his purpose, for in the case of fossil fish, the parts which are the basis of his system often remain, when even the skeleton is gone. And we may here sgan refer to a principle of the classificatory sciences, which we cannot make too prominent;-all arrangements and nomenclatures are good, which enable us to assert general propositions. Tried by this test, we cannot fail to set a high value on the arrangement of M. Agassiz; for propositions of the most striking generality respecting fossil remains of fish, of which geologists before had never dreamt, are enunciated by means of his groups and names. Thus only the two first orders, the Placoidians and Ganoidians, existed before the commencement of the cretaceous formation: the third and fourth orders, the Ctenordians and Cydordians, which contain three-fourths of the eight thousand known species of living Fishes, appear for the first time in the cretaceous formation: and other geological relations of these orders, no less remarkable, have been ascertained by M. Agassiz.

But we have now, I trust, pursued these sciences of classification sufficiently far, and it is time for us to enter upon that higher domain, of Physiology, to which, as we have said, Zoology so irresistably di-

rects us.

[2nd Ed.] [I have retained the remarks which I ventured at first to make on the System of M. Agassiz; but I believe the opinion of the most philosophical ichthyologists to be that Cuvier's System was too exclusively based on the internal skeleton, as Agassiz's

on the external skeleton. In some degree, both tems have been superseded, while all that was true each has been retained. Mr. Owen, in his Lectures Vertebrata (1846), takes Cuvierian characters from endo-skeleton, Agassizian ones from the exoiston, Linnsean ones from the ventral fins, Mullerian from the air-bladder, and combines them by the at of his own researches, with the view of forming a tem more truly natural than any preceding one. As I have said above, naturalists, in their progress wards a Natural System, are guided by physiological istions, latently in Botany, but conspicuously in ology. From the epoch of Cavier's Regne Animal, progress of Systematic Zoology is inseparably deident on the progress of Comparative Anatomy, nce I have placed Cuvier's Classification of animal me in the next Book, which treats of Physiology.

BOOK XVII.

ORGANICAL SCIENCES.

HISTORY OF PHYSIOLOGY

AND

COMPARATIVE ANATOMY.

Our body's vital plan,
And from the first dim hidden germ unfolds
The perfect limbs of man.
Who, who can pierce the secret! tell us how
Something is drawn from nought,
Life from the inert mass! Who, Lord! but thou,
Whose hand the whole has wrought!
Of this corporeal substance, still to be,
Thine eye a survey took;
And all my members, yet unformed by thee,
Were written in thy book.

PSALM CXXXIX. 13-16.

INTRODUCTION.

Of the Organical Sciences.

THOUGH the general notion of life is acknowledged by the most profound philosophers to be dim and mysterious, even up to the present time; and must, in the early stages of human speculation, have been still more obscure and confused; it was sufficient, even then, to give interest and connexion to men's observations upon their own bodies and those of other ammals. It was seen, that in living things, certain peculiar processes were constantly repeated, as those of breathing and of taking food, for example; and that a certain conformation of the parts of the animal was subservient to these processes; and thus were gradually formed the notions of Function and of Organization. And the sciences of which these notions formed the basis are clearly distinguishable from all those which we have hitherto considered. We conceive an organized body to be one in which the parts are there for the sake of the whole, in a manner different from any mechanical or chemical connexion; we conceive a function to be not merely a process of change, but of change connected with the general vital process. When mechanical or chemical processes occur in the living body, they are instrumental to, and directed by, the peculiar powers of life. The sciences which thus consider organization and vital functions may be termed organical sciences.

When men began to speculate concerning such subjects, the general mode of apprehending the process in the cases of some functions, appeared to be almost obvious, thus it was conceived that the growth of animals arose from their frame appropriating to itself a part of the substance of the food through the various

passages of the body. Under the influence of such general conceptions, speculative men were naturally led to endeavour to obtain more clear and definite views of the course of each of such processes, and of the mode in which the separate parts contributed to it. Along with the observation of the living person, the more searching examination which could be carried on in the dead body, and the comparison of various kinds of animals, soon showed that this pursuit was rich in knowledge and in interest. Moreover, besides the interest which the mere speculative faculty gave to this study, the Art of Healing added to it a great practical value; and the effects of diseases and of medicines supplied new materials and new motives for

the reasonings of the philosopher.

In this manner anatomy or physiology may be considered as a science which began to be cultivated in the earliest periods of civilization. Like most other ancient sciences, its career has been one of perpetual though variable progress; and as in others, so in this, each step has implied those which had been previously made, and cannot be understood aright except we understand them. Moreover, the steps of this advance have been very many and diverse; the cultivators of anatomy have in all ages been numerous and laborious; the subject is one of vast extent and complexity; almost every generation had added something to the current knowledge of its details; and the general speculations of physiologists have been subtle, bold, and learned. It must, therefore, be difficult or imporsible for a person who has not studied the science with professional diligence and professional advantages, to form just judgments of the value of the discoveries of various ages and persons, and to arrange them in their due relation to each other. To this we may add, that though all the discoveries which have been made with respect to particular functions or organizations are understood to be subordinate to one general science, the Philosophy of Life, yet the principles and doctrines of this science nowhere exist in a shape generally received and assented to among physiologists; and

have not, in this science, the advantage which the others we have possessed;—of discerning the firection of its first movements, by knowing the to which they ultimately tend,—of running on the earlier discoveries, and thus looking them face, and reading their true features. With the discoveries, all that we can have to say respective history of Physiology must need great indul-

on the part of the reader.

here, as in other cases, we may, by guiding our by those of the greatest and most philosophical who have made the subject their study, hope to material errours. Nor can we well evade making tempt. To obtain some simple and consistent for the progress of physiological science, is in ghest degree important to the completion of our of the progress of physical science. For the Mogical or organical sciences form a class to the classes already treated of, the mechanical, ical, and classificatory sciences, are subordinate miliary. Again, another circumstance which physiology an important part of our survey of knowledge, is, that we have here a science is concerned, indeed, about material combibut in which we are led almost beyond the of the material world, into the region of tion and perception, thought and will. Such a implation may offer some suggestions which may re us for the transition from physical to metaspeculations.

the survey which we must, for such purposes, of the progress of physiology, it is by no means may that we should exhaust the subject, and pt to give the history of every branch of the ledge of the phenomena and laws of hving ares. It will be sufficient, if we follow a few of nos of such researches, which may be considered amples of the whole. We see that life is accompand and sustained by many processes, which at first themselves to our notice as separate functions, for they may afterwards be found to be connected.

and identified; such are feeling, digestion, respiration, the action of the heart and pulse, generation, perception, voluntary motion. The analysis of any one of these functions may be pursued separately. And since in this, as in all genume sciences, our knowledge becomes real and scientific, only in so far as it is verified in particular facts, and thus established in general propositions, such an original separation of the subjects of research is requisite to a true representation of the growth of real knowledge. The loose hypotheses and systems, concerning the connexion of different vital faculties and the general nature of living things, which have often been promulgated, must be excluded from this part of our plan. not deny all value and merit to such speculations, but they cannot be admitted in the earlier stages of the history of physiology, treated of as an inductive science. If the doctrines so propounded have a solid and permanent truth, they will again come before us when we have travelled through the range of more himited truths, and are prepared to ascend with security and certainty into the higher region of general physiclogical principles. If they cannot be arrived at by such a road, they are then, however plausible and pleasing, no portion of that real and progressive science with which alone our history is concerned.

We proceed, therefore, to trace the establishment of some of the more limited but certain doctrines of

physiology.

CHAPTER I.

MOTION.

-Knowledge of Galen and his Predecessors.

carliest conceptions which men entertained of power of moving their own members, they thad no thought of any mechanism or organiwhich this was effected. The foot and the less than the head, were seen to be endowed s; and this pervading life semed sufficiently to the power of motion in each part of the frame, its being held necessary to seek out a special the will, or instruments by which its impulses ade effective. But the slightest inspection of danimals showed that their limbs were formed rious and complex collection of cordage, and ications of various kinds, running along and ing the bones of the skeleton. These cords and rications we now distinguish as muscles, nerves, steries, &c.; and among these, we assign to the the office of moving the parts to which they iched, as cords move the parts of a machine. this action of the muscles on the bones may pear very obvious, it was, probably, not at first d. It is observed that Homer, who describes ands which are inflicted in his battles with so pparent anatomical precision, nowhere employs d muscle. And even Hippocrates of Cos, the lebrated physician of antiquity, is held to have distinct conception of such an organ.1 He employs the word flesh when he means muscle, first explanation of the latter word $(\mu \bar{\nu}_{\xi})$ occurs purious work ascribed to him. For nerves,

Bprengel, Geschichte der Areneikunde, 1. 38a.

sinews, ligaments,2 he uses indiscriminately the same terms; (τόνος or νεύρον;) and of these nerves (νεύρα) he asserts that they contract the lumbs. Nor do we find much more distinctness on this subject even in Aristotle, a generation or two later. 'The origin of the reipa,' he says, is from the heart; they connect the bones, and surround the joints.' It is clear that he means here the muscles, and therefore it is with injustice that he has been accused of the gross errour of deriving the nerves from the heart. And he is held to have really had the merit's of discovering the nerves of sensation, which he calls the 'canals of the brain' (moon row eyeroakov); but the analysis of the mechanism of motion is left by him almost untouched. Perhaps his want of sound mechanical notions, and his constant straining after verbal generalities, and systematic classfications of the widest kind, supply the true account of his thus missing the solution of one of the simplest problems of Anatomy.

In this, however, as in other subjects, his immediate predecessors were far from remedying the deficiencies of his doctrines. Those who professed to study physiology and medicine were, for the most part, studious only to frame some general system of abstract principles, which might give an appearance of connexion and profundity to their tenets. In this manner the successors of Hippocrates became a medical school, of great note in its day, designated as the Dogmatic school; in opposition to which arose an Empiric sect, who professed to deduce their modes of cure, not from theoretical dogmas, but from experience. These rival parties prevailed principally in Asia Minor and Egypt, during the time of Alexander's successors, a period rich in names, but poor in discoveries; and we find no clear evidence of any decided advance in anatomy,

such as we are here attempting to trace.

The victories of Luculius and Pompeius, in Greece and Asia, made the Romans acquainted with the

Sprengel, Gesch. Arz. 1. 395.
 Hist. Anim. ili 5.
 Sprengel, Gesch. Arz. i. 583.

THE ORGANS OF VOLUNTARY MOTION. 321

rack philosophy; and the consequence soon was, that hoals of philosophers, rhetoricians, poets, and phylians streamed from Greece, Asia Minor, and Egypt, Rome and Italy, to traffic their knowledge and hair arts for Roman wealth. Among these, was one areon whose name makes a great figure in the history medicine, Asclepiades of Prusa in Bithynia. This man appears to have been a quack, with the usual adownients of his class;—boldness, singularity, a contemptuous rejection of all previously esteemed opinions, mew classification of diseases, a new list of medicines, and the assertion of some wonderful cures. He would be not such accounts, deserve a place in the history of tence, but that he became the founder of a new school, the Methodic, which professed to hold itself separate

th from the Dogmatics and the Empirics.

I have noticed these schools of medicine, because, bough I am not able to state distinctly their respective perits in the cultivation of anatomy, a great progress that science was undoubtedly made during their iomination, of which the praise must, I conceive, be some way divided among them. The amount of his progress we are able to estimate, when we come to he works of Galen, who flourished under the Antonines, and died about A.D. 203. The following passage from works will show that this progress in knowledge not made without the usual condition of laborious and careful experiment, while it implies the curious not of such experiment being conducted by means of limily tradition and instruction, so as to give rise to caste of dissectors. In the opening of his Second Book On Anatomical Manipulations, he speaks thus if his predecessors: 'I do not blame the ancients, who did not write books on anatomical manipulation; shough I praise Marinus, who did. For it was supertuous for them to compose such records for themselves ar others, while they were, from their childhood, exersised by their parents in dissecting, just as familiarly s in writing and reading; so that there was no more

Sprangel, Gesch. Ars. 11. 5.

fear of their forgetting their anatomy, than of forgetting their alphabet. But when grown men, as well as children, were taught, this thorough discipline fell off; and, the art being carried out of the family of the Asclepiads, and declining by repeated transmission,

books became necessary for the student.'

That the general structure of the animal frame. composed of bones and muscles, was known with great accuracy before the time of Galen, is manifest from the nature of the mistakes and deficiencies of his predecessors which he finds it necessary to notice. Thus he observes, that some anatomists have made one muscle into two, from its baving two heads;—that they have overlooked some of the muscles in the face of an apa in consequence of not akinning the animal with their own hauds; and the like. Such remarks imply that the current knowledge of this kind was tolerably complete. Galen's own views of the general mechanical structure of an animal are very clear and sound. The skeleton, he observes, discharges, the office of the pole of a tent, or the walls of a house. With respect to the action of the muscles, his views were anatomically and mechanically correct; in some instances, he showed what this action was, by severing the muscle. He himself added considerably to the existing knowledge of this subject; and his discoveries and descriptions, even of very minute parts of the muscular system, are spoken of with praise by modern anatomists.

We may consider, therefore, that the doctrine of the muscular system, as a collection of cords and sheets by the contraction of which the parts of the body are moved and supported, was firmly established, and completely followed into detail, by Galen and his predecessors. But there is another class of organs connected with voluntary motion, the nerves, and we must for a moment trace the opinions which prevailed respecting these. Aristotle, as we have said, noticed some of the nerves of sensation. But Herophilus.

⁷ De Anatom. Administ. 1, 2.

Bprengel, il. 157.

a lived in Egypt in the time of the first Ptolemy. tinguished nerves as the organs of the will, to and fus, who hved in the time of Trajan, 11 divides the ves into sensitive and motive, and derives them all in the brain. But this did not imply that men had distinguished the nerves from the muscles. lon maintained that every muscle consists of a bundle perves and sinews.12 But the important points, necessity of the nerve, and the origination of all apparatus of motion from the brain, he insists on with great clearness and force. Thus he proved necessity experimentally, by cutting through some the bundles of nerves,13 and thus preventing the responding motions. And it is, he says,1+ allowed all, both physicians and philosophers, that where origin of the nerve is, there the seat of the soul πιμονικόν τῆς ψυχῆς) must be: now this, he adds, is in brain, and not in the heart.

Thus the general construction and arrangement of organization by which voluntary motion is effected, well made out at the time of Galen, and is found tinctly delivered in his works. We cannot, perhaps, tly ascribe any large portion of the general discovery him: indeed, the conception of the mechanism of akeleton and muscles was probably so gradually delded in the minds of anatomical students, that it ald be difficult, even if we knew the labours of each caon, to select one, as peculiarly the author of the covery. But it is clear that all those who did maially contribute to the establishment of this doctrine. net have possessed the qualifications which we find Galen for such a task; namely, clear mechanical wa of what the tensions of collections of strings ald do, and an exact practical acquaintance with the menlar cordage which exists in the animal frame :short, in this as in other instances of real advance in bace, there must have been clear ideas and real facts.

unity of thought and extent of observation, brought into contact.

Sect. 2.—Recognition of Final Causes in Physiology.
Galen.

THERE is one idea which the researches of the physiclogist and the anatomist so constantly force upon him. that he cannot help assuming it as one of the guide of his speculations; I mean, the idea of a purpose, or as it is called in Aristotelian phrase, a final cause, in the arrangements of the animal frame. sible to doubt that the motive nerves run along the limbs, in order that they may convey to the muscles the impulses of the will; and that the muscles are attached to the bones, in order that they may move and support them. This conviction prevails so steadily among anatomists, that even when the use of any part is altogether unknown, it is still taken for granted that it has some use. The development of this conviction. -of a purpose in the parts of animals, -of a function to which each portion of the organization is subservient -contributed greatly to the progress of physiology; for it constantly urged men forwards in their researches respecting each organ, till some definite view of its purpose was obtained. The assumption of hypothetical final causes in Physics may have been, as Bacon assert it to have been, prejudicial to science, but the assumption of unknown final causes in Physiology, has given rise to the science. The two branches of speculation, Physics and Physiology, were equally led, by every nev phenomenon, to ask their question, 'Why?' But, in the former case, 'why' meant 'through what cause ! in the latter, 'for what end?' And though it may be possible to introduce into physiology the doctrine of efficient causes, such a step can never obliterate the obligations which the science owes to the pervading conception of a purpose contained in all organization.

This conception makes its appearance very carly. Indeed, without any special study of our structure, the thought, that we are fearfully and wonderfully made.

brees itself upon men, with a mysterious impressivesess, as a suggestion of our Maker. In this bearing, the thought is developed to a considerable extent in the well-known passage in Xenophon's Conversations Socrates. Nor did it ever lose its hold on soberminded and instructed men. The Epicureans, indeed, eld that the eye was not made for seeing, nor the ear or hearing; and Asclepiades, whom we have already mentioned as an impudent pretender, adopted this rild dogma. 16 Such assertions required no labour. It is easy,' says Galen, 16 'for people like Asclepades, when they come to any difficulty, to say that Nature worked to no purpose.' The great anatomist himelf pursues his subject in a very different temper. In a well-known passage, he breaks out into an enthulastic scorn of the folly of the atheistical notions. 17 Try,' he says, 'if you can imagine a shoe made with half the skill which appears in the skin of the foot. some one had spoken of a structure of the human body which he would have preferred to that which it now has. 'See,' Galen exclaims, after pointing out the absurdity of the imaginary scheme, 'see what brutishbess there is in this wish. But if I were to spend more words on such cattle, reasonable men might blame me for desecrating my work, which I regard as religious hymn in honour of the Creator,'

Galen was from the first highly esteemed as an material. He was originally of Pergamus; and after receiving the instructions of many medical and philophical professors, and especially of those of Alexandria, which was then the metropolis of the learned and scientific world, he came to Rome, where his reputation was soon so great as to excite the envy and hatred of the Roman physicians. The emperors Marcus Aurelius and Lucius Verus would have retained him near them; but he preferred pursuing his travels, directed principally by curiosity. When he died, he laft behind him numerous works, all of them of great

⁴ Sprengel, il. 15. 18 De Une Part v. 5, (on the kidneys.)
17 De Une Part, iii 10.

value for the light they throw on the him anatomy and medicine; and these were for period the storehouse of all the most important mical knowledge which the world possessed. time of intellectual barrenness and servility. the Arabians and the Europeans of the dark writings of Galen had almost unquestioned rity,18 and it was only by an uncommon a independent thinking that Abdollatif vent assert, that even Galen's assertions must give the evidence of the senses. In more model when Vesalius, in the sixteenth century, accus of mistakes, he drew upon himself the hostilit whole body of physicians. Yet the mistal such as might have been pointed out and con without acrimony, if, in times of revolution, and moderation were possible; but an impai the superstition of tradition on the part of vators, and an alarm of the subversion of all retruths on the part of the established teachers. and pervert all such discussions. charge against Galen is, that his dissections formed upon animals, and not upon the humi Galen himself speaks of the dissection of apes familiar employment, and states that he kills by drowning. The natural difficulties which, in ages, have prevented the unlimited prosecution d dissection, operated strongly among the auch it would have been difficult, under such circum to proceed more judiciously than Galen did.

I shall now proceed to the history of the of another and less obvious function, the circulthe blood, which belongs to modern times.

¹⁹ Sprengel, il 359. 19 Cuv Lecone sur l'Hist. des Sc. 1

CHAPTER II.

DECOVERY OF THE CIRCULATION OF THE BLOOD.

Sect. 1 .- Prelude to the Discovery.

HE blood-vessels, the veins and arteries, are as evident and peculiar in their appearance as the cles; but their function is by no means so obvious. pocrates did not discriminate Veins and Arteries; are called by the same name $(\phi \lambda i \beta \epsilon_0)$; and the of from which artery comes (aprophy) means, in his ks, the windpipe. Aristotle, scanty as was his wledge of the vessels of the body, has yet the merit aving traced the origin of all the veins to the heart. expressly contradicts those of his predecessors who derived the veins from the head, and refers to ection for the proof. If the book On the Breath be raine (which is doubted), Aristotle was aware of distruction between veins and arteries. 'Every lary,' it is there asserted, 'is accompanied by a vein; former are filled only with breath or air.' But ether or no this passage be Aristotle's, he held mions equally erroneous, as, that the windpipe conair into the heart.4 Galeno was far from having respecting the blood-vessels, as sound as those ich he entertained concerning the muscles. He d the liver to be the origin of the veins, and the art of the arteries. He was, however, acquainted th their junctions, or anastomoses. But we find no sterial advance in the knowledge of this subject, till overleap the blank of the middle ages, and reach dawn of modern science.

The father of modern anatomy is held to be Mon-

⁴ Spr. 1. 501.

dino, who dissected and taught at Bologna in 1315. Some writers have traced in him the rudiments of the doctrine of the circulation of the blood, for be says, that the heart transmits blood to the lungs. But it is allowed, that he afterwards destroys the ment of his remark, by repeating the old assertion that the left ventricle ought to contain spirit or air, which it

generates from the blood.

Anatomy was cultivated with great diligence and talent in Italy by Achillini, Carpa, and Messa, and in France by Sylvius and Stephanus (Dubois and Etienne). Yet still these empty assumptions respecting the heart and blood-vessels kept their ground. Vesalius, a native of Brussels, has been termed the founder of human anatomy, and his great work De Humani Corporis Fabrica is, even yet, a splendid monument of art, as well as science. It is said that his figures were designed by Titian; and if this be not exactly true, says Cuvier,7 they must, at least, be from the pencil of one of the most distinguished pupils of the great painter; for to this day, though we have more finished drawings, we have no designs that are more artistlike. Fallopius, who succeeded Vesalius at Padua, made some additions to the researches of his predecessor; but in his treatise De Principio Venarum, it is clearly seen 8 that the circulation of the blood was unknown to him. Eustachius also, whom Cavier groups with Vesahus and Fallopius, as the three great founders of modern anatomy, wrote a treatise on the vein azygos, which is a little treatise on comparative anatomy; but the discovery of the functions of the veins came from a different quarter.

The unfortunate Servetus, who was burnt at Geneva as a heretic in 1553, is the first person who speaks distinctly of the small circulation, or that which carries the blood from the heart to the lungs, and back again to the heart. His work entitled Christianismi Resti-

Encyc Brit. 692, Anatomy.

8 Cuv. Sc. Nat. p. 32.

9 Ib. p. 34.

tutio was also burnt; and only two copies are known to have escaped the flames. It is in this work that he esserts the doctrine in question, as a collateral argument or illustration of his subject. 'The communication between the right and left ventricle of the heart, is made, he says, 'not as is commonly believed, through the partition of the heart, but by a remarkable artifice (magno artificio) the blood is carried from the right ventricle by a long circuit through the lungs; is elaborated by the lungs, made yellow, and transfused from the vena arteriosa into the arteria venosa.' This truth is, however, mixed with various of the traditional fancies concerning the 'vital spirit, which has its origin in the left ventricle.' It may be doubted, also, how far Servetus formed his opimon upon conjecture, and on a hypothetical view of the formation of this vital spirit. And we may, perhaps, more justly ascribe the real establishment of the pulmonary circulation as an inductive truth, to Realdus Columbus, a pupil and successor of Vesalius at Padua, who published a work De Re Anatomica in 1559, in which he claims this discovery as his own. 10

Andrew Cæsalpinus, who has already come under our notice as one of the fathers of modern inductive science, both by his metaphysical and his physical speculations, described the pulmonary circulation still more completely in his Quastiones Perspatetica, and even seemed to be on the eve of discovering the great circulation, for he remarked the swelling of veins below ligatures, and inferred from it a refluent motion of blood in these vessels.11 But another discovery of structure was needed, to prepare the way for this discovery of function, and this was made by Fabricius of Acquapendente, who succeeded in the grand list of great professors at Padua, and taught there for fifty years. 12 Sylvius had discovered the existence of the valves of the veins; but Fabricius remarked that they are all turned towards the heart. Combining this disposition with that of the valves of the heart, and with the absence of valves in the arteries, he might have come to the conclusion 13 that the blood moves in a different direction in the arteries and in the veius, and might thus have discovered the circulation: but the glory was reserved for William Harvey: so true is it, observes Cuvier, that we are often on the brink of a discovery without suspecting that we are so:—so true is it, we may add, that a certain succession of time and of persons is generally necessary to familiarize men with one thought, before they can advance to that which is the next in order.

Sect. 2.—The Discovery of the Circulation made by Harvey.

WILLIAM HARVEY was born in 1578 at Folkestone in Kent. 4 He first studied at Cambridge: he afterwards went to Padua, where the celebrity of Fabricius of Acquapendente attracted from all parts those who wished to be instructed in anatomy and physiologi-In this city, excited by the discovery of the valves of the veins, which his master had recently made, and reflecting on the direction of the valves which are at the entrance of the veins into the heart, and at the ent of the arteries from it, he conceived the idea of making experiments, in order to determine what is the course of the blood in its vessels. He found that when he tied up veins in various animals, they swelled below the ligature, or in the part furthest from the heart; while arteries, with a like ligature, swelled on the side next the heart. Combining these facts with the direction of the valves, he came to the conclusion that the blood is impelled, by the left side of the heart, in the arteries to the extremities, and thence returns by the veins into the right side of the heart. He showed, too, how this was confirmed by the phenomena of the pulse, and by the results of opening the vessels. He proved, also, that the circulation of the lungs is a continuation of the larger circulation, and thus the whole doctrine of the double circulation was established.

Harvey's experiments had been made in 1616 and 1618; it is commonly said that he first promulgated his opinion in 1619; but the manuscript of the lectures, delivered by him as lecturer to the College of Physicians, is extant in the British Museum, and, containing the propositions on which the doctrine is founded, refers them to April, 1616. It was not till 1628 that he published, at Frankfort, his Exercitatio Anatomica de Motu Cordis et Sanguinis; but he there observes that he had for above nine years confirmed and illustrated his opinion in his lectures, by arguments grounded upon ocular demonstration.

Sect. 3.—Reception of the Discovery.

WITHOUT dwelling long upon the circumstances of the general reception of this doctrine, we may observe that it was, for the most part, readily accepted by his countrymen, but that abroad it had to encounter considerable opposition. Although, as we have seen, his predecessors had approached so near to the discovery, men's minds were by no means as yet prepared to receive it. Several physicians denied the truth of the opinion, among whom the most eminent was Riolan, professor at the Collège de France. Other writers, as usually happens in the case of great discoveries, asserted that the doctrine was ancient, and even that it was known to Hippocrates. Harvey defended his opinion with spirit and temper; yet he appears to have retained a lively recollection of the disagreeable nature of the struggles in which he was thus involved. At a later period of his life, Ent, 25 one of his admirers, who visited him, and urged him to publish the researches on generation, on which he had long been engaged, gives this account of the manner in which he received the proposal: 'And would you then advise me, (smilingly replies the doctor,) to quit the tranquillity of this haven, wherein I now calmly spend my days, and again commit myself to the unfaithful ocean? You

¹⁵ Epist. Dedic. to Anatom. Exercit.

are not ignorant how great troubles my lucubrations, formerly published, have raised. Better it is, certainly, at some time, to endeavour to grow wise at home a private, than by the hasty divulgation of such things to the knowledge whereof you have attained with vast labour, to stir up tempests that may deprive you of

your leisure and quiet for the future.'

His merits were, however, soon generally recognized. He was 16 made physician to James the First, and afterwards to Charles the First, and attended that unfortunate monarch in the civil war. He had the permission of the parliament to accompany the king on his leaving London; but this did not protect him from having his house plundered in his absence, not only of its furniture, but, which he felt more, of the records of his experiments. In 1652, his brethren of the College of Physicians placed a marble bust of him in their hall, with an inscription recording his discoveries; and two years later, he was nominated to the office of President of the College, which however he declined in consequence of his age and infirmities. His doctrine soon acquired popular currency; it was, for instance, taken by Descartes 17 as the basis of his physiology in his work On Man, and Harvey had the pleasure, which is often denied to discoverers, of seeing his discovery generally adopted during his lifetime.

Sect. 4.—Bearing of the Discovery on the Progress of Physiology.

In considering the intellectual processes by which Harvey's discoveries were made, it is impossible not to notice, that the recognition of a creative purpose, which, as we have said, appears in all sound physiological reasonings, prevails eminently here. 'I remember,' says Boyle, 'that when I asked our famous Harvey what were the things that induced him to think of a circulation of the blood, he answered me,

that when he took notice that the valves in the veins of so many parts of the body were so placed, that they gave a free passage to the blood towards the heart, but opposed the passage of the venal blood the contrary way, he was incited to imagine that so provident a cause as Nature had not placed so many valves without design and no design seemed more probable than that the blood should be sent through the arteries, and return through the veins, whose valves did not

oppose its course that way.'

We may notice further, that this discovery implied the usual conditions, distinct general notions, careful observation of many facts, and the mental act of bringing together these elements of truth. Harvey must have possessed clear views of the motions and pressures of a fluid circulating in ramifying tubes, to enable him to see how the position of valves, the pulnation of the heart, the effects of ligatures, of bleeding, and of other circumstances, ought to manifest themnelves in order to confirm his view. That he referred to a multiplied and varied experience for the evidence that it was so confirmed, we have already said. Like all the best philosophers of his time, he insists rigidly upon the necessity of such experience. 'In every science,' he says, 18 be it what it will, a diligent observation is requisite, and sense itself must be frequently consulted. We must not rely upon other men's experience, but our own, without which no man is a proper disciple of any part of natural knowledge.' And by publishing his experiments, he trusts, he adds, that he has enabled his reader 'to be an equitable umpire between Aristotle and Galen; or rather, he might have said, to see how, in the promotion of science, sense and reason, observation and invention, have a mutual need of each other.

We may observe further, that though Harvey's glory, in the case now before us, rested upon his having proved the reality of certain mechanical move-

in Generation of Animals, Pref.

ments and actions in the blood, this discovery, and all other physiological truths, necessarily involved the assumption of some peculiar agency belonging to living things, different both from mechanical agency, and from chemical, and in short, something vital, and not physical merely. For when it was seen that the pulsation of the heart, its systole and diastole, caused the circulation of the blood, it might still be asked, what force caused this constantly-recurring contraction and expansion. And again, circulation is closely connected with respiration; the blood is, by the circulation, carried to the lungs, and is there, according to the expression of Columbus and Harvey, mixed with air. But by what mechanism does this mixture take place, and what is the real nature of it? And when succeeding researches had enabled physiologists to give an answer to this question, as far as chemical relations go, and to say that the change consists in the abstraction of the carbon from the blood by means of the oxygen of the atmosphere; they were still only led to ask further, how this chemical change was effected, and how such a change of the blood fitted it for its uses. Every function of which we explain the course, the mechanism, or the chemistry, is connected with other functions,—is subservient to them, and they to it; and all together are parts of the general vital system of the animal, ministering to its life, but deriving their activity from the life. Life is not a collection of forces, or polarities, or affinities, such as any of the physical or chemical sciences contemplate, it has powers of its own, which often supersede those subordinate relations, and in the cases where men have traced such agents in the animal frame, they have always seen, and usually acknowledged, that these agents were ministerial to some higher agency, more difficult to trace than these, but more truly the cause of the phenomena.

The discovery of the mechanical and chemical conditions of the vital functions, as a step in physiology, may be compared to the discovery of the laws of phenomena in the heavens by Kepler and his predecessors,

while the discovery of the force by which they were produced was still reserved in mystery for Newton to bring to light. The subordinate relation of the facts, their dependence on space and time, their reduction to order and cycle, had been fully performed, but the reference of them to distinct ideas of causation, their interpretation as the results of mechanical force, was omitted or attempted in vain. The very notion of such Force, and of the manner in which motions were determined by it, was in the highest degree vague and vacillating; and a century was requisite, as we have seen, to give to the notion that clearness and fixity which made the Mechanics of the Heavens a possible science. In like manner, the notion of Life, and of Vital Forces, is still too obscure to be steadily held. We cannot connect it distinctly with severe inductions from facts. We can trace the motions of the animal fluids, as Kepler traced the motions of the planets; but when we seek to render a reason for these motions, like him, we recur to terms of a wide and profound, but mysterious import; to Virtues, Influences, undefined Yet we are not, on this account, to despair. The very instance to which I am referring shows us how rich is the promise of the future. Why, says Cuvier, 19 may not Natural History one day have its Newton? The idea of the vital forces may gradually become so clear and definite as to be available in science; and future generations may include, in their physiology, propositions elevated as far above the circulation of the blood, as the doctrine of universal gravitation goes beyond the explanation of the heavenly motions by epicycles.

If, by what has been said, I have exemplified sufficiently the nature of those steps in physiology, which, like the discovery of the Circulation, give an explanation of the process of some of the animal functions, it is not necessary for me to dwell longer on the subject; for to write a history, or even a sketch of the history of Physiology, would suit neither my powers nor my

¹⁵ Oston Fost, Introd.

purpose. Some further analysis of the general views which have been promulgated by the most eminest physiologists, may perhaps be attempted in treating of the Philosophy of Inductive Science; but the estimation of the value of recent speculations and investigations must be left to those who have made this vast subject the study of their lives. A few brief notices may, however, be here introduced.

CHAPTER IIL

Discovery of the Motion of the Chyle, and consequent Speculations.

Sect. 1 .- The Discovery of the Motion of the Chyle.

T may have been observed in the previous course of I this History of the Sciences, that the discoveries in each science have a peculiar physiognomy: something of a common type may be traced in the progress of each of the theories belonging to the same department of knowledge. We may notice something of this common form in the various branches of physiological speculation. In most, or all of them, we have, as we have noticed the case to be with respect to the circulation of the blood, clear and certain discoveries of mechanical and chemical processes, succeeded by speculations far more obscure, doubtful, and vague, respecting the relation of these changes to the laws of life. This feature in the history of physiology may be further instanced, (it shall be done very briefly,) in one or two other cases. And we may observe, that the lesson which we are to collect from this narrative, is by no means that we are to confine ourselves to the positive discovery, and reject all the less clear and certain speculations. To do this, would be to lose most of the chances of ulterior progress; for though it may be, that our conceptions of the nature of organic life are not yet sufficiently precise and steady to become the guides to positive inductive truths, still the only way in which these peculiar physiological ideas can be made more distinct and precise, and thus brought more nearly into a scientific form, is by this struggle with our ignorance or imperfect knowledge. This is the lesson we have learnt from the history of physical astronomy and other sciences. We must strive to refer facts which are known and understood, to higher principles, of which we cannot doubt the existence, and of which, in some degree, we can see the place; however dim and shadowy may be the glimpses we have hitherto been able to obtain of their forms. We may often fail in such attempts, but without the attempt we can never succeed.

That the food is received into the stomach, there undergoes a change of its consistence, and is then propelled along the intestines, are obvious facts in the animal economy. But a discovery made in the course of the seventeenth century brought into clearer light the sequel of this series of processes, and its connexion with other functions. In the year 1622, Asellius or Aselli discovered certain minute vessels, termed lacteals, which absorb a white liquid (the chyle) from the bowels, and pour it into the blood. These vessels had, in fact, been discovered by Eristratus, in the ancient world,2 in the time of Ptolemy; but Aselli was the first modern who attended to them. He described them in a treatise, entitled De Venis Lactes, cum figuris elegantissimis, printed at Milan in 1627. the year after the death of the author. The work is remarkable as the first which exhibits coloured anatomical figures; the arteries and the veins are represented in red, the lacteals in black.

Eustachius,3 at an earlier period, had described (in the horse) the thoracic duct by which the chyle is poured into the subclavian vein, on the right side of the neck. But this description did not excite so much notice as to prevent its being forgotten, and rediscovered in 1650, after the knowledge of the circulation of the blood had given more importance to such a discovery. Up to this time,4 it had been supposed that the lacteals carried the chyle to the liver, and that the blood was manufactured there. This opinion had prevailed in all the works of the ancients and moderns; its falsity was discovered by Pecquet, a French physician, and pub-

Mayo, Physiology, p. 156. S Cav. Hist p. 34.

² Cuv. Hat Se p 50. ⁴ 1b, p, 365.

in which are discovered a receptacle of the chyle, unknown till then, and the vessel which conveys it to the subclavian vein. Pecquet himself, and other anatomists, soon connected this discovery with the doctrine, then recently promulgated, of the circulation of the blood. In 1665, these vessels, and the hymphatics which are connected with them, were further illustrated by Ruysch in his exhibition of their valves (Dilucidatio valvularum in vasis lymphaticis et lacteis).

Sect. 2.—The Consequent Speculations. Hypotheses of Digestion.

Thus it was shown that aliments taken into the stomach are, by its action, made to produce chyme; from the chyme, gradually changed in its progress through the intestines, chyle is absorbed by the lacteals; and this, poured into the blood by the thoracic duct, repairs the waste and nourishes the growth of the animal. But by what powers is the food made to undergo these transformations? Can we explain them on mechanical or on chemical principles? Here we come to a part of physiology less certain than the discovery of vessels, or of the motion of fluids. We have a number of opinions on the subject, but no universally acknowledged truth. We have a collection of Hypotheses of Digestion and Nutrition.

I shall confine myself to the former class; and without dwelling long upon these, I shall mention some of
them. The philosophers of the Academy del Cimento,
and several others, having experimented on the stomach
of gallinaceous birds, and observed the astonishing
force with which it breaks and grinds substances, were
led to consider the digestion which takes place in the
stomach as a kind of trituration. Other writers thought
it was more properly described as fermentation; others
again spoke of it as a putrefaction. Varignon gave a

⁶ Bourdon, Physiol. Comp p 514.

merely physical account of the first part of the process. maintaining that the division of the aliments was to effect of the disengagement of the air introduced into the stomach, and dilated by the heat of the body. The opinion that digestion is a solution of the food by the gastric juice has been more extensively entertained.

Spallanzani and others made many experiments on this subject. Yet it is denied by the best physiologists, that the changes of digestion can be adequately represented as chemical changes only. The nerves of the stomach (the meumo-gostric) are said to be essential to digestion. Dr. Wilson Philip has asserted that the influence of these nerves, when they are destroyed, may be replaced by a galvanic current.6 This might give rise to a supposition that digestion depends on galvanism. Yet we cannot doubt that all these hypotheses,-mechanical, physical, chemical, galvanic-are altogether insufficient. 'The stomach must have,' se Dr. Prout says,7 'the power of organizing and vitalizing the different elementary substances. It is impossible to imagine that this organizing agency of the stomach can be chemical. This agency is vital, and its nature completely unknown.'

Miller (Manual of Physiology, B. lii. Sect 1, Chap. lii.) speaks of and other physiologists have re-Dr Wilson Phil.p's assertion that the nerves of the stomach being extensive scale, and have found out, and a galvanic current kept no effect of this kind. up in them, digestion is still ac-

complished. He states that he peated such experiments on #4

I Bridgescater Tr. p. 493.

CHAPTER IV.

EXAMINATION OF THE PROCESS OF REPRODUCTION IN ANIMALS AND PLANTS, AND CONSEQUENT SPECULA-

Sect. 1.—The Examination of the Process of Reproduction in Animals.

IT would not, perhaps, be necessary to give any more examples of what has hitherto been the general process of investigations on each branch of physiology; or to illustrate further the combination which such researches present, of certain with uncertain knowledge,—of solid discoveries of organs and processes, succeeded by indefinite and doubtful speculations concerning vital forces. But the reproduction of organized beings is not only a subject of so much interest as to require some notice, but also offers to us laws and principles which include both the vegetable and the animal kingdom; and which, therefore, are requisite to render intelligible the most general views to which we can attain, respecting the world of organization.

The facts and laws of reproduction were first studied in detail in animals. The subject appears to have attracted the attention of some of the philosophers of antiquity in an extraordinary degree; and indeed we may easily imagine that they hoped, by following this path, if any, to solve the mystery of creation. Aristotle appears to have pursued it with peculiar complacency; and his great work On Animals contains an extraordinary collection of curious observations relative to this subject. He had learnt the modes of reproduction of most of the animals with which he was acquainted; and his work is still, as a writer of our own times has

Bourdon, p 161.

said,2 'original after so many copies, and young after two thousand years.' His observations referred prucipally to the external circumstances of generation the anatomical examination was left to his successors. Without dwelling on the intermediate labours, we come to modern times, and find that this examination owes its greatest advance to those who had the greatest share in the discovery of the circulation of the blood -Fabricius of Acquapendente, and Harvey. The former, published a valuable work on the Egg and the Chick. In this are given, for the first time, figures representing the development of the chick, from its almost imperceptible beginning, to the moment when it breaks the shell. Harvey pursued the researches of his teacher. Charles' the First had supplied him with the means of making the experiments which his purpose required, by sacrificing a great number of the deer in Windsor Park in the state of gestation, but his principal researches were those respecting the egg, in which he followed out the views of Fabricius. In the troubles which succeeded the death of the unfortunate Charles, the house of Harvey was pillaged; and he lost the whole of the labours he had bestowed on the generation of insects. His work, Exercitations & Generatione Animalium, was published at London in 1651; it is more detailed and perfect than that of Fabricius; but the author was prevented by the unsettled condition of the country from getting figures engraved to accompany his descriptions.

Many succeeding anatomists pursued the examination of the series of changes in generation, and of the organs which are concerned in them, especially Malpighi, who employed the microscope in this investigation, and whose work on the Chick was published in 1673. It is impossible to give here any general view of the result of these laborious series of researches but we may observe, that they led to an extremely minute and exact survey of all the parts of the fectus, its en-

² Bourdon, p. 101.

³ Cuv. Hat Sc Agt p 46.

⁴ Ib. p. 53.

velopes and appendages, and, of course, to a designation of these by appropriate names. These names afterwards served to mark the attempts which were made to carry the analogy of animal generation into the vegetable

kingdom.

There is one generalization of Harvey which deserves notice. He was led by his researches to the conclusion, that all living things may be properly said to come from eggs: 'Omne vivum ex ovo.' Thus not only do oviparous animals produce by means of eggs, but in those which are viviparous, the process of generation begins with the development of a small vesicle. which comes from the ovary, and which exists before the embryo: and thus viviparous or suckling-beasts, not withstanding their name, are born from eggs, as well as birds, fishes, and reptiles.6 This principle also excludes that supposed production of organized beings without parents (of worms in corrupted matter, for instance,) which was formerly called spontaneous generation, and the best physiologists of modern times agree in denying the reality of such a mode of generation.7

Sect. 2.—The Examination of the Process of Reproduction in Vegetables.

The extension of the analogies of animal generation to the vegetable world was far from obvious. This extension was however made;—with reference to the embryo plant, principally by the microscopic observers, Nehemiah Grew. Marcello Malpighi, and Antony Leeuwenhoek;—with respect to the existence of the sexes, by Linnseus and his predecessors.

The microscopic labours of Grew and Malpighi were patronized by the Royal Society of London in its earliest youth. Grew's book, The Anatomy of Plants, was ordered to be printed in 1670. It contains plates representing extremely well the process of germination in various seeds, and the author's observations exhibit

[.] Exerc lxili.

a very clear conception of the relation and analogies of different portions of the seed. On the day on which the copy of this work was laid before the Society, a communication from Malpighi of Bologna, Anatoma Plantarum Idea, stated his researches, and promised figures which should illustrate them. Both authors afterwards went on with a long train of valuable observations which they published at various times, and which contain much that has since become a permanent

portion of the science.

Both Grew and Malpighi were, as we have remarked, led to apply to vegetable generation many terms which imply an analogy with the generation of animals. Thus, Grew terms the innermost coat of the seed, the secundane; speaks of the navel-fibres, &c. Many more such terms have been added by other writers. And, as has been observed by a modern physiologist, the resemblance is striking. Both in the vegetable seed and in the fertilized animal egg, we have an embryo, chalaze, a placenta, an umbilical cord, a cicatricula, an amnios, membranes, nourishing vessels. The cotyledom of the seed are the equivalent of the ritellus of birds, or of the umbilical vesicle of sucking-beasts; the allnumes or perisperm of the grain is analogous to the white of the egg of birds, or the allantoid of viviparous animals.

Sexes of Plants.—The attribution of sexes to plants, is a notion which was very early adopted, but only gradually unfolded into distinctness and generality. The ancients were acquainted with the fecundation of vegetables. Empedocles, Aristotle, Theophrastus, Pliny, and some of the poets, make mention of it: but their notions were very incomplete, and the conception was again lost in the general shipwreck of human knowledge. A Latin poem, composed in the fifteenth century by Jovianus Pontanus, the preceptor of Alphonso, King of Naples, is the first modern work in which mention is made of the sex of plants. Pontanus sings the loves of two date-palms, which grew at the distance of fifteen leagues from each other: the male

^{*} Bourdon, p. 384.

Mirbel, E7. II. 538.

did not prevent the female at Otranto. The distance did not prevent the female from becoming fmitful, as soon as the palms had raised their heads above the surrounding trees, so that nothing intervened directly between them, or, to speak with the poet, so that they were able to see each other.

Zaluzian, a botanist who lived at the end of the afteenth century, says that the greater part of the species of plants are androgynes, that is, have the properties of the male and of the female united in the same plant; but that some species have the two sexes in ceparate individuals, and he adduces a passage of Pliny relative to the fecundation of the date-palm. John Baubin, in the middle of the seventeenth century, cites the expressions of Zaluzian, and forty years later, a professor of Tubingen, Rudolph Jacob Camerarius, pointed out clearly the organs of generation, and proved by experiments on the mulberry, on maize, and on the plant called Mercury (mercurialis), that when by any means the action of the stamina upon the pistils is intercepted, the seeds are barren. Camerarius, therefore, a philosopher in other respects of little note, has the honour assigned him of being the author of the discovery of the sexes of plants in modern times. 10

The ment of this discovery will, perhaps, appear more considerable when it is recollected that it was rejected at first by very eminent botanists. Thus Tournefort, misled by insufficient experiments, maintained that the stamina are excretory organs; and Reaumur, at the beginning of the eighteenth century, inclined to the same doctrine. Upon this, Geoffroy, an apothecary at Paris, scrutinized afresh the sexual organs, he examined the various forms of the pollen, already observed by Grew and Malpighi; he pointed out the excretory canal, which descends through the atyle, and the micropyle, or minute orifice in the coats of the ovule, which is opposite to the extremity of this canal; though he committed some mistakes with regard to the nature of the pollen. Soon afterwards, Sebastian

Vaillant, the pupil of Tournefort, but the corrector of his errour on this subject, explained in his public lectures the phenomenon of the fecundation of plants, described the explosion of the anthers, and showed that the florets of composite flowers, though formed on the type of an androgynous flower, are sometimes male, sometimes female, and sometimes neuter.

M. A too A

a

q

ñ

But though the sexes of plants had thus been noticed, the subject drew far more attention when Linnaus made the sexual parts the basis of his classification Camerarius and Burkard had already entertained such a thought, but it was Linnaus who carried it into effect, and thus made the notion of the sexes of vegetables almost as familiar to us as that of the sexes of animals.

Sect. 3.—The Consequent Speculations. - Hypotheses of Generation.

THE views of the processes of generation, and of their analogies throughout the whole of the organic world, which were thus established and diffused, form as important and substantial part of our physiological knowledge. That a number of curious but doubtful hypotheses should be put forwards, for the purpose of giving further significance and connexion to these discoveries, was to be expected. We must content ourselves with speaking of these very briefly. We have such hypotheses in the earliest antiquity of Greece, for as we have already said, the speculations of cosmogony were the source of the Greek philosophy, and the laws of generation appeared to offer the best promise of knowledge respecting the mystery of creation. Hippocrates explained the production of a new animal by the mixture of seed of the parents; and the offspring was male or female as the seminal principle of the father or of the mother was the more powerful. According to Aristotle, the mother supplied the matter, and the father the form. Harvey's doctrine was, that

ovary of the female is fertilized by a seminal contugion produced by the seed of the male. But an opinion which obtained far more general reception was, that the embryo pre existed in the mother, before any union of the sexes.11 It is easy to see that this doctrine is accompanied with great difficulties;12 for if the mother, at the beginning of life, contain in her the embryos of all her future children; these embryos again must contain the children which they are capable of producing; and so on indefinitely; and thus each female of each species contains in herself the germs of infinite future generations. The perplexity which is involved in this notion of an endless series of creatures, thus encased one within the other, has naturally driven inquirers to attempt other suppositions. The microscopic researches of Leeuwenhoek and others led them to the belief that there are certain animalcules contained in the seed of the male, which are the main agents in the work of reproduction. This system ascribes almost everything to the male, as the one last mentioned does to the female. Finally, we have the system of Buffon,—the famous hypothesis of organic molecules. That philosopher asserted that he found, by the aid of the microscope, all nature full of moving globules, which he conceived to be, not animals as Leeuwenhoek imagined, but bodies capable of producing, by their combination, either animals or vegetables, in short, all organized bodies. These globules he called organic molecules,13 And if we inquire how these organic molecules, proceeding from all parts of the two parents, unite into a whole, as perfect as either of the progenitors, Buffon answers, that this is the effect of an interior mould; that is, of a system of internal laws and tendencies which determine the form of the result as an external mould determines the shape of the cast.

An admirer of Buffon, who has well shown the untenable character of this system, has urged, as a kind

¹¹ Bourdon, p. 204.

¹² lb, p 209.

of apology for the promulgation of the hypothesis,14 that at the period when its author wrote, he could not present his facts with any hope of being attended to, if he did not connect them by some common tie, some dominant idea which might gratify the mind; and that acting under this necessity, he did well to substitute for the extant theories, already superannuated and confessedly imperfect, conjectures more original and more probable. Without dissenting from this view, we may observe, that Buffon's theory, like those which preceded it, is excusable, and even deserving of admiration, so far as it groups the facts consistently, because in doing this, it exhibits the necessity, which the physiclogical speculator ought to feel, of aspiring to dehiate and solid general principles; and that thus, though the theory may not be established as true, it may be useful by bringing into view the real nature and application of such principles.

It is, therefore, according to our views, unphilosophical to derive despair, instead of hope, from the imperfect success of Buffon and his predecessors. Yet this is what is done by the writer to whom we refer. For me,' says he,15 I avow that, after having long meditated on the system of Buffon,—a system so remarkable, so ingenious, so well matured, so wonderfully connected in all its parts, at first sight so probable.—I confess that, after this long study, and the researches which it requires, I have conceived in consequence, a distrust of myself, a skepticism, a disdain of hypothetical systems, a decided predilection and exclusive taste for pure and rational observation, in short, a dis-

beartening, which I had never felt before.'

The best remedy of such feelings is to be found in the history of science. Kepler, when he had been driven to reject the solid epicycles of the ancients, or a person who had admired Kepler as M. Bourdon admires Buffon, but who saw that his magnetic virtue was an untenable fiction, might, in the same manner,

¹⁴ Bourdon, p. 121.

THE PROCESS OF REPRODUCTION.

of the

have thrown up all hope of a sound theory of the causes of the celestial motions. But astronomers were too wise and too fortunate to yield to such despondency. The predecessors of Newton substituted a solid science of Mechanics for the vague notions of Kepler; and the time soon came when Newton himself reduced the motions of the heavens to a Law as distinctly conceived as the Motions had been before.

CHAPTER V.

Examination of the Nervous System, and Consequent Speculations.

Sect. 1 .- The Examination of the Nervous System.

It is hardly necessary to illustrate by further examples the manner in which anatomical observation has produced conjectural and hypothetical attempts to connect structure and action with some higher principle, of a more peculiarly physiological kind. But it may still be instructive to notice a case in which the principle, which is thus brought into view, is far more completely elevated above the domain of matter and mechanism than in those we have yet considered.— case where we have not only Irritation, but Sensation;—not only Life, but Consciousness and Will. A part of science in which suggestions present themselves, brings us, in a very striking manner, to the passage from the physical to the hyperphysical sciences.

We have seen already (chap. 1) that Galen and his predecessors had satisfied themselves that the nerves are the channels of perception; a doctrine which had been distinctly taught by Herophilus! in the Alexandrian school. Herophilus, however, still combined, under this common name of Nerves, the Tendons; though he distinguished such Nerves from those which arise from the brain and the spinal marrow, and which are subservient to the will. In Galen's time this subject had been prosecuted more into detail. That anatomist has left a Treatise expressly upon The Anatomy of the Nerves; in which he describes the successive Pairs of Nerves: thus, the First Pair are the visual nerves: and we see, in the language which

Galen uses, the evidence of the care and interest with which he had himself examined them. 'These nerves.' he says, 'are not resolved into many fibres, like all the other nerves, when they reach the organs to which they belong; but spread out in a different and very remarkable manner, which it is not easy to describe or to believe, without actually seeing it.' He then gives a description of the retina. In like manner he describes the Second Pair, which is distributed to the muscles of the eyes; the Third and Fourth Pairs, which go to the tongue and palate; and so on to the Seventh Pair. This division into Seven Pairs was established by Marinus,2 but Vesalius found it to be incomplete. The examination which is the basis of the anatomical enumeration of the Nerves at present recognized, was that of Willis. His book. entitled Cerebri Anatome, cui accessit Nervorum descriptio et usus, appeared at London in 1664. He made important additions to the knowledge of this subject." Thus he is the first who describes in a distinct manuer what has been called the Nervous Center,4 the pyramidal eminences which, according to more recent anatomists. are the communication of the brain with the spinal marrow: and of which the Decussation, described by Santorini, affords the explanation of the action of a part of the brain upon the nerves of the opposite side. Willis proved also that the Rete Mirabile, the remarkable net-work of arteries at the base of the brain, observed by the ancients in ruminating animals, does not exist in man. He described the different Pairs of Nerves with more care than his predecessors; and his mode of numbering them is employed up to the present time. He calls the Olfactory Nerves the First Pair, previously to him, these were not reckoned a Pair: and thus the optic nerves were, as we have seen, called the first. He added the Sixth and the Ninth Pairs, which the anatomists who preceded him did not reckon. Willis also examined carefully the different Ganglions, or knots which occur upon the nerves. He traced them wherever they were to be found, and he gave a general

² Die Sc. Med. xxxv. 467.

figure of what Cuvier calls the nervous skeleton, very superior to that of Vesalius, which was coarse and inexact. Willis also made various efforts to show the connexion of the parts of the brain. In the earner periods of anatomy, the brain had been examined by slicing it, so as to obtain a section. Varolius enderyoured to unravel it, and was followed by Wuls. Vicq d'Azyr, in modern times, has carried the method of section to greater perfection than had before been given it,5 as Vieussens and Gall have done with respect to the method of Varolius and Willis. Recently, Professor Chanssier makes three kinds of Nerves .the Encephalic, which proceed from the head, and are twelve on each side; -the Rachidian, which proceed from the spinal marrow, and are thirty on each side, and Compound Nerves, among which is the Great Sym-

pathetic Nerve.

One of the most important steps ever made in our knowledge of the nerves is, the distinction which Bichat is supposed to have established, of a ganglionic system, and a cerebral system. And we may add, to the discoveries in nervous anatomy, the remarkable one, made in our own time, that the two offices of conducting the motive impressions from the central seat of the will to the muscles, and of propagating sensations from the surface of the body and the external organs of sense to the sentient mind reside in two distinct portions of the nervous substance -a discovery which has been declared? to be 'doubtless the most important accession to physiological (anatomical) knowledge since the time of Harvey.' This doctrine was first published and taught by Sir Charles Bell: after an interval of some years, it was more distinctly delivered in the publications of Mr. John Shaw, Sir C. Bell's pupil. Soon afterwards it was further confirmed, and some part of the evidence corrected, by Mr. Mayo, another pupil of Sir C. Bell, and by M. Majendie.8

⁴ Cuv. p. 40.

⁸ As anthority for the expressions which I have now used in the text, I will mention Muller's Manual of Physiology . (4th edition,

Sect. 2.—The Consequent Speculations. Hypotheses respecting Life, Sensation, and Volition.

I SHALL not attempt to explain the details of these anatomical investigations; and I shall speak very briefly of the speculations which have been suggested by the obvious subservience of the nerves to life, sennation, and volition. Some general inferences from their distribution were sufficiently obvious; as, that the seat of sensation and volution is in the brain. Galen begins his work, On the Anatomy of the Nerves, thus: 'That none of the members of the animal either exercises voluntary motion, or receives sensation, and that if the nerve be cut, the part immediately becomes inert and insensible, is acknowledged by all physicians, But that the origin of the nerves is partly from the brain, and partly from the spinal marrow, I proceed to explain.' And in his work On the Doctrines of

1844) In Book of Section a, Shaw, in 1839, published A Nartion and Motion, Miller says, Charles Bell in the Nervous System, Charles Bell was the first who in which it appears that Sir had the ingenious thought that Charles Bell had further exof the spine-those which are fur- to his pupils (p 89), and that one same theory. But Mr. Alexander and Mr. Mayo,

Chap 1, On the Nerves of Sensa- rative of the Discoveries of Sir the posterior roots of the nerves pounded his views in his lectures nished with a ganglion-govern of these, Mr. John Shaw, had in sensation only , that the auterior various publications, in 1821 and roots are appointed for motion, 1822, further insisted upon the and that the primitive fibres of same views, especially in a Methese roots, after being united in most On Partial Paralysis (p. 75). a single nervo is cord, are mingled MM Mayo and Mojendie both together in order to supply the published Memoirs in August, wants of the skin and muscles. 1823; and in these and subsequent He developed this idea in a little works confirmed the doctrine of work, (An Idea of a new Anatomy Bell. Mr Alexander Shaw states of the Brain, London, (811,) which (p. 97), that a mistake of Sir was not intended to travel beyond Charles Bell's, in an experiment the circle of his friends.' Muller which he had made to prove his goes on to say, that eleven years doctrine, was discovered through later, Majendle prosecuted the the joint labours of M. Majendie Plate and Hippocrates, he proves at great length that the brain is the origin of sensation and motion, refutite the opinions of earlier days, as that of Chrysn pur who placed the hegemonic, or master-principle of the soul, in the heart. But though Galen thought that the rational soul resides in the brain, he was disposed to agree with the poets and philosophers, according whom the heart is the seat of courage and anger, and the liver the seat of love. 11 The faculties of the soul were by succeeding physiologists confined to the brust but the disposition still showed itself, to attribute to them distinct localities. Thus Willis 12 places the imagination in the corpus callosum, the memory in the folds of the hemispheres, the perception in the corpus striatum. In more recent times, a system founded upon a similar view has been further developed by Gall and his followers. The germ of Gall's system may be considered as contained in that of Willis, for Gall represents the hemispheres as the folds of a great membrane which is capable of being unwrapped and spread out, and places the different faculties of man in the different regions of this membrane. The chase which intervenes between matter and motion on the one side, and thought and feeling on the other. brought into view by all such systems; but none of the hypotheses which they involve can effectually bridge it over.

The same observation may be made respecting the attempts to explain the manner in which the nerves operate as the instruments of sensation and volume. Perhaps a real step was made by Glisson. To professor of medicine in the University of Cambridge, who distinguished in the fibres of the muscles of motion to peculiar property, different from any merely mechanical or physical action. His work On the Nature of the Energetic Substance, or on the Life of Nature and of its Three First Faculties, The Perceptive, Appearance,

⁹ Lib. vii.

¹⁰ Cuy. Sc. Not p. 434.

Motive, which was published in 1672, is rather etaphysical than physiological. But the principles hich he establishes in this treatise he applies more pecially to physiology in a treatise On the Stomach and Intestines (Amsterdam, 1677) In this he ascribes the fibres of the animal body a peculiar power which ealls Irritability. He divides irritation into natural, ital, and animal, and he points out, though briefly, he gradual differences of irritability in different gans. 'It is hardly comprehensible,' says Sprengel, 'A how this lucid and excellent notion of the Cambridge eacher was not accepted with greater alacrity, and farther unfolded by his contemporaries.' It has, how-

ever, since been universally adopted.

But though the discrimination of muscular irritaility as a peculiar power, might be a useful step in vsiological research, the explanations hitherto offered, of the way in which the nerves operate on this irritafility, and discharge their other offices, present only a eries of hypotheses. Glisson 15 assumed the existence of certain vital spirits, which, according to him, are a mild, sweet fluid, resembling the spirituous part of white of egg, and residing in the nerves. This hypothesis, of a very subtle humour or spirit existing in the nerves, was indeed very early taken up.16 This pervous spirit had been compared to air by Erasistratus, Asclepiades, Galen, and others. The chemical tendencies of the seventeenth century led to its being described as acid, sulphureous, or nitrous. At the and of that century, the hypothesis of an ether attracted much notice as a means of accounting for many phenomena; and this ether was identified with the nervous fluid. Newton himself inclines to this view. in the remarkable Queries which are annexed to his Opticks. After ascribing many physical effects to his ether, he adds (Query 23), 'Is not vision performed chiefly by the vibrations of this medium, excited in the bottom of the eye by the rays of light, and proparated through the solid, pellucid, and uniform capilla-

¹⁴ Spr. iv. 47. 1 lb. iv. 38. 16 Halter, Physiol. iv. 365.

menta of the nerves into the place of sensation? And (Query 24), 'Is not animal motion performed by the vibrations of this medium, excited in the brain to the power of the will, and propagated from thence through the capillamenta of the nerves into the muscles to contracting and dilating them? And an option approaching this has been adopted by some of the greatest of modern physiologists; as Haller, who sava that, though it is more easy to find what this nervous spirit is not than what it is, he conceives that, while it must be far too fine to be perceived by the seusci it must yet be more gross than fire, magnetism, a electricity; so that it may be contained in vessels and confined by boundaries. And Cuvier speaks to the same effect; 18 'There is a great probability that it is by an imponderable fluid that the nerve acts on the fibre, and that this nervous fluid is drawn from the blood, and secreted by the medullary matter.'

Without presuming to dissent from such authorities on a point of anatomical probability, we may venture to observe, that these hypotheses do not tend at all to elucidate the physiological principle which here involved; for this principle cannot be mechanical chemical, or physical, and therefore cannot be better understood by embodying it in a fluid; the difficulty we have in conceiving what the moving force u. not got rid of by explaining the machinery by which it is merely transferred. In tracing the phenomens of sensation and volition to their cause, it is clear that we must call in some peculiar and hyperphysical principle. The hypothesis of a fluid is not made more satisfactory by attenuating the fluid; it becomes subtle, spirituous, ethereal, imponderable, to no purpost it must cease to be a fluid, before its motions can become sensation and volition. This, indeed, is acknowledged by most physiologists; and strongly stated by Cuvier. 18 'The impression of external objects upon the ME, the production of a sensation, of an

 ¹⁷ Physiol. iv. 381, lib. x. sect. vili. § 15.
 18 Règne Animal, Introd. p. 30.
 19 To. p. 47.

is a mystery impenetrable for our thoughts.' in several places, by the use of this peculiar the me,' (le moi,) for the sentient and volent by, he marks, with peculiar appropriateness and that phraseology borrowed from the world of er will, in this subject, no longer answer our ose. We have here to go from Nouns to Profrom Things to Persons. We pass from the to the Soul, from Physics to Metaphysics. We bome to the borders of material philosophy; the step is into the domain of Thought and Mind. therefore, we begin to feel that we have reached coundaries of our present subject. The examinaof that which lies beyond them must be reserved ph.losophy of another kind, and for the labours be future; if we are ever enabled to make the apt to extend into that loftier and wider scene, principles which we gather on the ground we are laboriously treading.

sch speculations as I have quoted respecting the ons fluid, proceeding from some of the greatest peophers who ever lived, prove only that hitherto indeavour to comprehend the mystery of percepand will, of life and thought, have been fruitless vain. Many anatomical truths have been disred, but, so far as our survey has yet gone, no ine physiological principle. All the trains of hological research which we have followed have in exact examination of organization and funcand have ended in wide conjectures and arbitrary theses. The stream of knowledge in all such cases ar and lively at its outset; but, instead of reachthe great ocean of the general truths of science, it adually spread abroad among sauds and deserts to course can be traced no longer.

therto, therefore, we must consider that we have to tell the story of the failures of physiological plation. But of late there have come into view use among physiologists certain principles which be considered as peculiar to organized subjects; of which the introduction forms a real advance in

organical science. Though these have hitherto between imperfectly developed, we must endeavour exhibit, in some measure, their history and bearing

[2nd Ed.] [In order to show that I am not unaw how imperfect the sketch given in this work is. History of Physiology, I may refer to the further & cussions on these subjects contained in the Philoson of the Inductive Sciences, Book ix. I have the (Chap. ii.) noticed the successive Biological Hypothe of the Mystical, the Introchemical, and Intromati matical Schools, the Vital-Fluid School, and the Pi chical School. I have (Chaps. iii., iv., v.) examin several of the attempts which have been made analyse the Idea of Life, to classify Vital Function and to form Ideas of Separate Vital Forces. I considered, in particular, the attempts to form a tinct conception of Assimilation and Secretion, Generation, and of Voluntary Motion; and I be (Chap. vi) further discussed the Idea of Final Can as employed in Biology.

CHAPTER VI.

AND METAMORPHOSED SYMMETRY.

-- Vegetable Morphology. Göthe. De Candolle.

ORE we proceed to consider the progress of inciples which belong to animal and human h as have just been pointed at, we must look for such doctrines, if any such there be, as apply all organized beings, conscious or unconscious, locomotive,—to the laws which regulate vegewell as animal forms and functions. Though very far from being able to present a clear and ted code of such laws, we may refer to one law, which appears to be of genuine authority didity; and which is worthy our attention as mple of a properly organical or physiological ple, distinct from all mechanical, chemical, or physical forces; and such as cannot even be red to be resolvable into those. I speak of the bey which produces such results as have been at together in recent speculations upon Mor-

may perhaps be regarded as indicating how ar are the principles of organic life, and how far ad from any mere mechanical action, that the g idea in these speculations was first strongly lectively apprehended, not by a laborious experiment and reasoner, but by a man of singularly briland creative fancy; not by a mathematician or at, but by a poet. And we may add further, his poet had already shown himself incapable of apprehending the relation of physical facts to principles; and had, in trying his powers on such the exhibited a signal instance of the ineffectual precise operation of the method of philosophizing

person of whom we speak, is John Wolfgang Goth who is held, by the unanimous voice of Europe, thave been one of the greatest poets of our own, or any time, and whose Doctrine of Colours we have already had to describe, in the History of Optics an entire failure. Yet his views on the laws which connect the forms of plants into one simple system have been generally accepted and followed up. We might almost be led to think that this writer's postical endowments had contributed to this scientific discovery,—the love of beauty of form, by fixing that the third of thought, by making constant development of a familiar process.

But though we cannot but remark the peculiarity of our being indebted to a poet for the discovery of a scientific principle, we must not forget that he bimed held, that in making this step, he had been guide not by his invention, but by observation. He repelled with extreme repugnance, the notion that he had substituted fancy for fact, or imposed ideal laws on actual

Dich verwirret, geliebte, die tausendfältige mischung

Name upon name thou hearest, and in thy dissatisfied hearing.

With a barbarian noise one drives another along

All the forms resemble, yet none is the same as another.

Thus the whole of the throng points at a deep hidden law.

Points at a sacred riddle. Oh! could I to thee, my beloved from Whisper the fortunate word by which the riddle is read.

We may quote some of the poet's own verses as an illustration his feelings on this subject. They are addressed to a lady

things. While he was earnestly pursuing his morphological speculations, he attempted to impress them upon Schiller. 'I expounded to him, in as lively a manner as possible, the metamorphosis of plants, drawing on paper, with many characteristic strokes, a symbolic plant before his eyes. He heard me,' Gothe says,2 with much interest and distinct comprehension; but when I had done, he shook his head, and said, 'That is not Experience; that is an Idea:' I stopt with some degree of irritation; for the point which separated us was marked most luminously by this expression.' And in the same work he relates his botanical studies and his habit of observation, from which it is easily seen that no common amount of knowledge and notice of details, were involved in the course of thought which led him to the principle of the Metamorphosis of Plants.

Before I state the history of this principle, I may be allowed to endeavour to communicate to the reader. to whom this subject is new, some conception of the principle itself. This will not be difficult, if he will imagine to himself a flower, for instance, a common wild-rose, or the blossom of an apple-tree, as consisting of a series of parts disposed in whorls, placed one over another on an axis. The lowest whorl is the calyx with its five sepals; above this is the corolla with its five petals; above this are a multitude of stamens, which may be considered as separate whorls of five each, often repeated; above these is a whorl composed of the ovaries, or what become the seed-vessels in the fruit, which are five united together in the apple, but indefinite in number and separate in the rose. Now the morphological view is this, - that the members of each of these whorls are in their nature identical, and the same as if they were whorls of ordinary leaves, brought together by the shortening their common axis, and modified in form by the successive elaboration of their nutriment. Further, according to this

view, a whorl of leaves itself is to be considered as

² Zur Morphologie, p 14.

identical with several detached leaves dispersed spirally along the axis, and brought together because the axis is shortened. Thus all the parts of a plant are, or at least represent, the successive metamorphoses of the same elementary member. The root-leaves thus pass into the common leaves;—these into bracteze,—these into the sepals;—these into the petals;—these into the stamens with their anthers;—these into the ovanes with their styles and stigmas,—these ultimately become the fruit; and thus we are finally led to the seed of a new plant.

Moreover the same notion of metamorphosis may be applied to explain the existence of flowers which are not symmetrical like those we have just referred to, but which have an irregular corolla, or calyx. The papilionaceous flower of the pea tribe, which is so markedly irregular, may be deduced by easy gradations from the regular flower, (through the mimosex.) by expanding one petal, joining together two others, and

THE RESERVE OF THE PARTY OF THE

modifying the form of the intermediate ones.

Without attempting to go into detail respecting the proofs of that identity of all the different organs, and all the different forms of plants, which is thus asserted, we may observe, that it rests on such grounds as these; -the transformations which the parts of flowers undergo by accidents of nutriment or exposure. Such changes, considered as monstrosities where they are very remarkable, show the tendencies and possibilities belonging to the organization in which they occur. For instance, the single wild-rose, by culture, transforms many of its numerous stamens into petals, and thus acquires the deeply folded flower of the double gardenrose. We cannot doubt of the reality of this change, for we often see stamens in which it is incomplete. In other cases we find petals becoming leaves, and a branch growing out of the center of the flower. Some peartrees, when in blossom, are remarkable for their tendency to such monstrosities. Again, we find that flowers which are usually irregular, occasionally become bregular,

Lindley, Nat. Syst. p 84.

and conversely. The common snap-dragon (Linaria vulgaris) affords a curious instance of this. The usual form of this plant is 'personate,' the corolla being divided into two lobes, which differ in form, and together present somewhat the appearance of an animal's face, and the upper portion of the corolla is prolonged backwards into a tube-like 'spur.' No flower can be more irregular; but there is a singular variety of this plant, termed Pelmia, in which the corolla is strictly symmetrical, consisting of a conical tube, narrowed in front, elongated behind into five equal apurs, and containing five stamens of equal length, instead of the two unequal pairs of the didynamous Linaria. These and the like appearances show that there is in nature a capacity for, and tendency to, such changes as the doctrine of metamorphosis asserts.

and his system was the result of his own independent course of thought. The view which it involved was not, however, absolutely new, though it had never before been unfolded in so distinct and persuasive a manner. Linnaeus considered the leaves, calyx, corolla, stamens, each as evolved in succession from the other; and spoke of it as prolepsis or anticipation, when the leaves changed accidentally into bracters, these into a calyx, this into a corolla, the corolla into stamens, or these into the pistil. And Caspar Wolf apprehended in a more general manner the same principle. 'In the whole plant,' says he, 'we see nothing but leaves and stalk;' and in order to prove what is the situation of the leaves in all their later forms, he adduces the coty-

ledons as the first leaves.

Gothe was led to his system on this subject by his general views of nature. He saw, he says, that a whole life of talent and labour was requisite to enable any one to arrange the infinitely copious organic forms of a single kingdom of nature. 'Yet I felt,' he adds, 'that

<sup>Henslow, Principles of Botany, p. 116.

Zur Morph. 1, 30.</sup>

for me there must be another way, analogous to the rest of my habits. The appearance of the changes, round and round, of organic creatures had taken strong hold on my mind. Imagination and Nature appeared to me to vie with each other which could go on most boldly yet most consistently.' His observation of nature, directed by such a thought, led him to the doc-

trine of the metamorphosis.

In a later republication of his work (Zur Morphologie, 1817.) he gives a very agreeable account of the various circumstances which affected the reception and progress of his doctrine. Willdenow's quoted him thus: 'The life of plants is, as Mr. Gothe very prettily says, an expansion and contraction, and these alternations make the various periods of life.' 'This 'prettily,' says Gothe, 'I can be well content with, but the 'egregie' of Usteri is much more pretty and obliging.' Usteri had used this term respecting Gothe in an edition of Jussieu.

The application of the notion of metamorphosis to the explanation of double and monstrous flowers had been made previously by Jussieu. Gothe's merit was to have referred to it the regular formation of the flower. And as Sprengel justly says,9 his view had so profound a meaning, made so strong an appeal by its simplicity, and was so fruitful in the most valuable consequences, that it was not to be wondered at if it occasioned further examination of the subject, although many persons pretend to slight it. The task of confirming and verifying the doctrine by a general application of it to all cases, a labour so important and necessary after the promulgation of any great principle, -Gothe himself did not execute. At first he collected specimens and made drawings with some such view,10 but he was interrupted and diverted to other matter. 'And now,' says he, in his later publication, 'when I look back on this undertaking, it is easy to see that the

⁹ Zur Morph. i. 121 ⁹ Gesch. Boton. ii 304.
¹⁰ Zur Morph. i. 129.

PRINCIPLE OF METAMORPHOSED SYMMETRY, 365

object which I had before my eyes was, for me, in my position, with my habits and mode of thinking, unattainable. For it was no less than this: that I was to take that which I had stated in general, and presented to the conception, to the mental intuition, in words; and that I should, in a particularly visible, orderly, and gradual manner, present it to the eye; so as to show to the outward sense that out of the germ of this idea might grow a tree of physiology fit to overshadow the world.

Voigt, professor at Jena, was one of the first who adopted Gothe's view into an elementary work, which he did in 1808. Other botanists laboured in the direction which had thus been pointed out. Of those who have thus contributed to the establishment and development of the metamorphic doctrine, Professor De Candolle, of Geneva, is perhaps the most important, His Theory of Developement rests upon two main principles, abortion and adhesion By considering some parts as degenerated or absent through the abortion of the buds which might have formed them, and other parts as adhering together, he holds that all plants may be reduced to perfect symmetry: and the actual and constant occurrence of such incidents is shown beyond all doubt. And thus the snap-dragon, of which we have spoken above, is derived from the Peloria, which is the normal condition of the flower, by the abortion of one stamen, and the degeneration of two others. Such examples are too numerous to need to be dwelt on.

Sect. 2.—Application of Vegetable Morphology.

THE doctrine, being thus fully established, has been applied to solve different problems in botany; for instance, to explain the structure of flowers which appear at first sight to deviate widely from the usual forms of the vegetable world. We have an instance of such an application in Mr. Robert Brown's explanation of the real structure of various plants which had been entirely misunderstood: as, for example, the genus Euphorbia.

In this plant he showed that what had been held to be a jointed filament, was a pedicel with a filament above it, the intermediate corolla having evanesced. Orchidea, (the orchis tribe.) he showed that the pecular structure of the plant arose from its having six stamens (two sets of three each), of which five are usually abortive. In Conifera, (the cone bearing trees,) it was made to appear that the seed was naked, while the accompanying appendage, corresponding to a seedvessel, assumed all forms, from a complete leaf to a mere scale. In like manner it was proved that the pappus, or down of composite plants, (as thistles,) is a

transformed calvx.

Along with this successful application of a profound principle, it was natural that other botanists should make similar attempts. Thus Mr. Lindley was led to take a view11 of the structure of Reseda (mignonette) different from that usually entertained, which, when published, attracted a good deal of attention, and gained some converts among the botanists of Germany and France. But in 1833, Mr. Lindley says, with great candour, 'Lately, Professor Henslow has satufactorily proved, in part by the aid of a monstresity in the common Mignonette, in part by a severe application of morphological rules, that my hypothesis must necessarily be false.' Such an agreement of different botanists respecting the consequences of morphological rules, proves the reality and universality of the rules.

We find, therefore, that a principle which we may call the Principle of Developed and Metamorphord Symmetry, is firmly established and recognized, and familiarly and successfully applied by botanists. it will be apparent, on reflection, that though symmetry is a notion which applies to inorganic as well as to organic things, and is, in fact, a conception of certain relations of space and position, such development and metamorphosis as are here spoken of, are ideas entirely

¹¹ Lindley, Brit. Assoc. Report, ill So.

PRINCIPLE OF METAMORPHOSED SYMMETRY. 367

different from any of those to which the physical sciences have led us in our previous survey; and are, in short, genuine organical or physiological ideas;—real elements of the philosophy of life.

We must, however imperfectly, endeavour to trace the application of this idea in the other great department of the world of life; we must follow the history of Animal Morphology.

CHAPTER VII.

PROGRESS OF ANIMAL MORPHOLOGY.

Sect. 1 .- Rise of Comparative Anatomy.

THE most general and constant relations of the I form of the organs, both in plants and animals, are the most natural grounds of classification Hence the first scientific classifications of animals are the first steps in animal morphology. At first, a zoology was constructed by arranging animals, as plants were at first arranged, according to their external parts. But in the course of the researches of the anatomsts of the seventeenth century, it was seen that the internal structure of animals offered resemblances and transtions of a far more coherent and philosophical kind, and the science of Comparative Anatomy rose into favour and importance. Among the main cultivators of this science' at the period just mentioned, we find Francis Redi, of Arezzo; Guichard Joseph Duvernay, who was for sixty years Professor of Anatomy at the Jardin du Roi at Paris, and during this lapse of time had for his pupils almost all the greatest anatomists of the greater part of the eighteenth century; Nehemah Grew, secretary to the Royal Society of London, whose Anatomy of Plants we have already noticed.

But Comparative Anatomy, which had been cultivated with ardour to the end of the seventeenth century, was, in some measure, neglected during the first two-thirds of the eighteenth. The progress of botany was, Cuvier sagaciously suggests, one cause of this, for that science had made its advances by confining itself to external characters, and rejecting anatomy; and though Linnæus acknowledged the dependence of zoology upon anatomy so far as to make

¹ Cur. Lecous sur l'Hist. des Sc. Not 414, 420.

² Cuy. Hist. Sc. Nat. 1. 301.

the number of teeth his characters, even this was felt, in his method, as a bold step. But his influence was soon opposed by that of Buffon, Daubenton, and Pallas; who again brought into view the importance of comparative anatomy in Zoology; at the same time that Haller proved how much might be learnt from it in Physiology. John Hunter in England, the two Munros in Scotland, Camper in Holland, and Vicq d'Azyr in France, were the first to follow the path thus pointed out. Camper threw the glance of genius on a host of interesting objects, but almost all that he produced was a number of sketches; Vicq d'Azyr, more assiduous, was stopt in the midst of a most brilliant career by a premature death.

Such is Cuvier's outline of the earlier history of comparative anatomy. We shall not go into detail upon this subject; but we may observe that such studies had fixed in the minds of naturalists the conviction of the possibility and the propriety of considering large divisions of the animal kingdom as modifications of one common type. Belon, as early as 1555, had placed the skeleton of a man and a bird side by side, and shown the correspondence of parts. So far as the case of vertebrated animals extends, this correspondence is generally allowed; although it required some ingenuity to detect its details in some cases; for instance, to see the analogy of parts between the head

of a man and of a fish.

In tracing these less obvious correspondencies, some surious steps have been made in recent times. And here we must, I conceive, again ascribe no small merit to the same remarkable man who, as we have already had to point out, gave so great an impulse to vegetable morphology. Gothe, whose talent and disposition for speculating on all parts of nature were truly admirable, was excited to the study of anatomy by his propinquity to the Duke of Weimar's cabinet of natural history. In 1786, he published a little essay, the object of which was to show that in man, as well as in beasts, the upper jaw contains an intermaxillary bone, although

YOL III.

the sutures are obliterated. After 1790, animated and impelled by the same passion for natural observe tion and for general views, which had produced by Metamorphosis of Plants, he pursued his speculation on these subjects eagerly and successfully. 1795, he published a Sketch of a Universal Introduction into Comparative Anatomy, beginning with Oster logy; in which he attempts to establish an 'osteological type,' to which skeletons of all animals may be referred I do not pretend that Gothe's anatomical works have had any influence on the progress of the science comparable with that which has been exercised by the labours of professional anatomists; but the ingenuty and value of the views which they contained was acknowledged by the best authorities; and the clearer introduction and application of the principle of developed and metamorphosed symmetry may be dated from about this time. Gothe declares that, at an early period of these speculations, he was convinced that the bony head of beasts is to be derived from six vertebræ. In 1807, Oken published a 'Program' On the Signification of the Bones of the Skull, in which he maintained that these bones are equivalent to far vertebræ; and Meckel, in his Comparative Anatomy, in 1811, also resolved the skull into vertebre. But Spir, in his elaborate work Cephalogenesis, in 1815, reduced the vertebræ of the head to three. 'Oken,' he says, published opinions merely theoretical, and const quently contrary to those maintained in this work which are drawn from observation.' This resolution of the head into vertebræ is assented to by many of the best physiologists, as explaining the distribution of the nerves, and other phenomena. Spix further extended the application of the vertebral theory to the heads of all classes of vertebrate animals; and Bojanus published a Memoir expressly on the vertebral structure of the skulls of fishes in Oken's Isis for 1818. Geoffrey Saint-Hilaire presented a lithographic plate to the

⁴ Zur Morphologie, 1. 234.

⁴ Ib 250.

rench Academy in February 1824, entitled Composion de la Tête osseuse chez l'Homme et les Animuux,
ad developed his views of the vertebral composition
I the skull in two Memoirs published in the Annales
Sciences Naturelles for 1824. We cannot fail to
acognize here the attempt to apply to the skeleton of
mimals the principle which leads botanists to consider
I the parts of a flower as transformations of the same
gans. How far the application of the principle, as
re proposed, is just, I must leave philosophical
hysiologists to decide.

By these and similar researches, it is held by the set physiologists that the skull of all vertebrate imals is pretty well reduced to a uniform structure, and the laws of its variations nearly determined.

The vertebrate animals being thus reduced to a ngle type, the question arises how far this can be one with regard to other animals, and how many uch types there are. And here we come to one of the important services which Cuvier rendered to natural history.

of Animals.—Cuvier.

Animals were divided by Lamarck into vertebrate and invertebrate; and the general analogies of all vertebrate animals are easily made manifest. But with the same animals are easily made manifest. But with the same are animals, the point is far from clear. Ouvier was the first to give a really philosophical view of the animal world in reference to the plan on which such animal is constructed. There are, he says, four such plans,—four forms on which animals appear to have been modelled; and of which the ulterior divisions, with whatever titles naturalists have decorated them, are only very slight modifications, founded on the development or addition of some parts which do not produce any essential change in the plan.

These four great branches of the animal world are

⁷ Cuy. Hist. Sc. Nat. id. 444.

the vertebrata, mollusca, articulata, radiata; and the differences of these are so important that a signi

explanation of them may be permitted.

The vertebrata are those animals which (as man ad other sucklers, birds, fishes, lizards, frogs, serpental have a back-bone and a skull with lateral appendance, within which the viscera are included, and to which the muscles are attached.

The mollusca, or soft animals, have no bony skeleton; the muscles are attached to the skin, which often includes stony plates called shells; such molluscs are shell fish; others are cuttle-fish, and many pulpy sanimals.

The articulata consist of crustacea, (lobsters, &c.) insects, spiders, and annulose worms, which consist of a head and a number of successive annular portions of the body jointed together, (to the interior of which the

muscles are attached,) whence the name.

Finally, the radiata include the animals known under the name of zoophytes. In the preceding three branches, the organs of motion and of sense were distributed symmetrically on the two sides of an axis, so that the animal has a right and a left side. In the radiata the similar members radiate from the axis in a circular manner, like the petals of a regular flower.

The whole value of such a classification cannot be understood without explaining its use in enabling in to give general descriptions, and general laws of the animal functions of the classes which it includes; but in the present part of our work our business is to exhibit it as an exemplification of the reduction of animals to laws of Symmetry. The bipartite Symmetry of the form of vertebrate and articulate animals is obvious; and the reduction of the various forms of such animals to a common type has been effected by attention to their anatomy, in a manner which has satisfied those who have best studied the subject. The molluses, especially those in which the head disappear, as oysters, or those which are rolled into a spiral, at snails, have a less obvious Symmetry, but here also we can apply certain general types. And the Symmetry

of the radiated zoophytes is of a nature quite different from all the rest, and appropriating as we have suggested, to the kind of Symmetry found in points. Some naturalists have doubted whether these anaphytes are not referrible to two types acrite or polytes and true

radiata,) rather than to one

This fourfold dryson was introduced by Currer II Before him, naturalists i clowed Linearia, and divided non-vertebrate animals into two timeses, insects and worms. 'I began, says (noter to attack that they of the subject, and offered another division it a Memour read at the Somety of Natura. History of Paris the 21st of Florest, in the year III of the Reputation, (May 10, 1795) printed in the Decase I accompanyon in this, I mark the characters and the musts of molluses, insects, worms, echipoderma, and garabittes. I distinguished the red-blooded worms or many sea, the a Memoir read to the Institute, the 11th Nivose, year X. (December 31, 1801). I afterwar is distributed these different classes into three branches each co-ordinate to the branch formed by the vertebrate animals, in a Memour read to the Institute in July, 1812, printed in the Annales de Mnorum d'Hutoire A aturelle, tom. xix.' His great systematic work, the Regne Animal, founded on this distribution, was published in 1817, and since that time the division has been commonly accepted among naturalists.

[2nd Ed.] The question of the Chasafication of Animals is discussed in the first of Prof. Owen's Lectures on the Invertebrate Animals (1843). Mr. Owen observes that the arrangement of animals into Vertebrate and Invertebrate which prevailed before Cuvier, was necessarily bad, inasmuch as no negative character in Zoology gives true natural groups. Hence the establishment of the sub-kingdoms, Mollusca, Articulata, Radiata, as co-ordinate with Vertebrata, according to the arrangement of the nervous system, was a most important advance. But Mr. Owen has seen reason to separate the Radiata of Cuvier into two

⁹ Brit. Assoc. Rep. 1v 227.

divisions; the Nematoneura, in which the nervous system can be traced in a filamentary form (including Echinoderma, Ciliobrachiata, Calelmintha, Rottfera,) and the Acrita or lowest division of the animal kingdom, including Acalepha, Nudibrachiata, Sterelmintha, Polygastria.]

Sect. 3.—Attempts to establish the Identity of the Types of Animal Forms.

SUPPOSING this great step in Zoology, of which we have given an account,—the reduction of all animals to four types or plans,-to be quite secure, we are then led to ask whether any further advance is posible; -- whether several of these types can be referred to one common form by any wider effort of generalize tion. On this question there has been a considerable difference of opinion. Geoffroy Saint-Hilaire, who had previously endeavoured to show that all vertebrate animals were constructed so exactly upon the same plan as to preserve the strictest analogy of parts in respect to their osteology, thought to extend thu unity of plan by demonstrating, that the hard parts of crustaceans and insects are still only modifications of the skeleton of higher animals, and that therefore the type of vertebrata must be made to include them also:—the segments of the articulata are held to be strictly analogous to the vertebre of the higher animals, and thus the former live within their vertebral column in the same manner as the latter has without it. Attempts have even been made to reduce molluscous and vertebrate animals to a community of type, as we shall see shortly.

Another application of the principle, according to which creatures the most different are developements of the same original type, may be discerned. In the doctrine, that the embryo of the higher forms of animal life passes by gradations through those forms

¹¹ Mr Jenyne, Brit. Assoc. Rep. iv. 150. ii Dr. Clark, Report, Ib. iv. 113.

which are permanent in inferior animals. Thus, according to this view, the human feetus assumes successively, the plan of the zoophyte, the worm, the fish, the turtle, the bird, the beast. But it has been well observed, that 'in these analogies we look in vain for the precision which can alone support the inference that has been deduced;'¹³ and that at each step, the higher embryo and the lower animal which it is supposed to resemble, differ in having each different

organs suited to their respective destinations.

Cuvier14 never assented to this view, nor to the attempts to refer the different divisions of his system to a common type. 'He could not admit,' says his biographer, 'that the lungs or gills of the vertebrates are in the same connexion as the branchize of molluscs and crustaceans, which in the one are situated at the base of the feet, or fixed on the feet themselves, and in the other often on the back or about the arms. He did not admit the analogy between the skeleton of the vertebrates and the skin of the articulates; he could not believe that the tenia and the sepia were constructed on the same plan, that there was a similarity of composition between the bird and the echinus, the whale and the snail; in spite of the skill with which some persons sought gradually to efface their discrepancies.'

Whether it may be possible to establish, among the four great divisions of the 'Animal Kingdom,' some analogies of a higher order than those which prevail within each division, I do not pretend to conjecture. If this can be done, it is clear that it must be by comparing the types of these divisions under their most general forms, and thus Cuvier's arrangement, so far as it is itself rightly founded on the unity of composition of each branch, is the surest step to the discovery of a unity pervading and uniting these branches. But though those who generalize surely, and those who generalize rapidly, may travel in the same direction, they soon separate so widely, that they

¹² Dr. Clark, p. 114.

^{1.} Laurillard, Elog. de Cueler, p. 66.

appear to move from each other. The partisans of a universal 'unity of composition' of animals, accused Cuvier of being too inert in following the progress of physiological and zoological science. Borrowing these illustration from the political parties of the times, they asserted that he belonged to the science of the rendance, not to the science of the movement. Such a charge was highly honourable to him; for no one acquainted with the history of zoology can doubt that he had a great share in the impulse by which the 'movement' was occasioned; or that he himself made a large advance with it; and it was because he was so poised by the vast mass of his knowledge, so temperate in his love of doubtful generalizations, that he was not swept on in the wilder part of the stream. To such a charge, moderate reformers, who appreciate the value of the good which exists, though they try to make it better, and who know the knowledge, thoughtfulness, and caution, which are needful in such a task, are naturally exposed. For us, who can only decide of such a subject by the general analogies of the history of science, it may suffice to say, that it appears doubtful whether the fundamental conceptions of affinity, analogy, transition, and developement, have yet been fixed in the minds of physiologists with sufficient firmness and clearness, or unfolded with sufficient consistency and generality, to make it likely that any great additional step of this kind can for some time be made.

We have here considered the doctrine of the identity of the seemingly various types of animal structure, as an attempt to extend the correspondencies which were the basis of Cuvier's division of the animal kingdom. But this doctrine has been put forward in another point of view, as the antithesis to the doctrine of final causes. This question is so important a one, that we cannot help attempting to give some view of its state and bearings.

CHAPTER VIII.

THE DOCTRINE OF FINAL CAUSES IN PHYSIOLOGY.

Sect. 1 .- Assertion of the Principle of Unity of Plan.

WE have repeatedly seen, in the course of our historical view of Physiology, that those who have studied the structure of animals and plants, have had a conviction forced upon them, that the organs are constructed and combined in subservience to the life and functions of the whole. The parts have a purpose, as well as a law; — we can trace Final Causes, as well as Laws of Causation. This principle is peculiar to physiology; and it might naturally be expected that, in the progress of the science, it would come under special consideration. This accordingly has happened; and the principle has been drawn into a prominent position by the struggle of two antagonist schools of physiclogists. On the one hand, it has been maintained that this doctrine of final causes is altogether unphilosophical, and requires to be replaced by a more comprehensive and profound principle: on the other hand, it is asserted that the doctrine is not only true, but that, in our own time, it has been fixed and developed so as to become the instrument of some of the most important discoveries which have been made. Of the views of these two schools we must endeavour to give some account.

The disciples of the former of the two schools express their tenets by the phrases unity of plan, unity of composition; and the more detailed development of these doctrines has been termed the Theory of Analogies, by Geoffroy Saint-Hilaire, who claims this theory as his own creation. According to this theory, the structure and functions of animals are to be studied by the guidance of their analogy only; our attention is to be turned, not to the fitness of the organization for any

end of life or action, but to its resemblance to other organizations by which it is gradually derived from

the original type.

According to the rival view of this subject, we must not assume, and cannot establish, that the plan of all animals is the same, or their composition similar. The existence of a single and universal system of analogies in the construction of all animals is entirely unproved, and therefore cannot be made our guide in the study of their properties. On the other hand, the plan of the animal, the purpose of its organization in the support of its life, the necessity of the functions to its existence, are truths which are irresistably apparent, and which may therefore be safely taken as the bases of our reasonings. This view has been put forward as the doctrine of the conditions of existence, it may also be described as the principle of a purpose in organization; the structure being considered as having the function for its end. We must say a few words on each of these views.

It had been pointed out by Cuvier, as we have seen in the last chapter, that the animal kingdom may be divided into four great branches; in each of which the plan of the animal is different, namely, vertebrata, articulata, mollusca, radiata. Now the question naturally occurs, is there really no resemblance of construction in these different classes? It was maintained by some, that there is such a resemblance. In 1820, M. Audonin, a young naturalist of Paris, endeavoured to fill up the chasm which separates insects from other animals; and by examining carefully the portions which compose the solid frame-work of insects, and following them through their various transformations in different classes, he conceived that he found relations of position and function, and often of number and form, which might be compared with the relations of the parts of the skeleton in vertebrate animals. He thought that the first segment of an insect, the head,2 represents one of the three vertebræ which, according to Spix and

¹ Cay Hist. Sc. Nat. ill. 442.

others, compose the vertebrate head: the second segment of the insects, (the prothorax of Audouin,) is, according to M. Geoffroy, the second vertebra of the head of the vertebrata, and so on. Upon this speculation Cuvier does not give any decided opinion; observing only, that even if false, it leads to active thought and useful research.

But when an attempt was further made to identify the plan of another branch of the animal world, the mollusca, with that of the vertebrata, the radical oppoposition between such views and those of Cuvier, broke

out into an animated controversy.

Two French anatomists, MM. Laurencet and Meyraux, presented to the Academy of Sciences, in 1830, a blemoir containing their views on the organization of molluscous animals; and on the sepia or cuttle-fish in particular, as one of the most complete examples of such animals. These creatures, indeed, though thus placed in the same division with shell-fish of the most defective organization and obscure structure, are far from being scantily organized. They have a brain, often eyes, and these, in the animals of this class, (cephalopoda) are more complicated than in any vertebrates, 5 they have sometimes ears, salivary glands, multiple stomachs, a considerable liver, a bile, a complete double circulation, provided with auricles and ventricles; in short, their vital activity is vigorous, and their senses are distinct.

But still, though this organization, in the abundance and diversity of its parta, approaches that of vertebrate animals, it had not been considered as composed in the same manner, or arranged in the same order. Cuvier had always maintained that the plan of molluscs is not a continuation of the plan of vertebrates.

MM. Laurencet and Meyranx, on the contrary, conceived that the sepia might be reduced to the type of

discutés en 1830, p. 68.

Cov Hist Sc. Nat iii. 441. Geoffroy Saint-Hilaire, Prin-Geoffroy Saint-Hilaire denies cipes de Philosophie Zoologique disthis Principes de Phil Zoologique cutés en 1830, p. 55.

a vertebrate creature, by considering the back-bone of the latter bent double backwards, so as to bring the root of the tail to the nape of the neck; the parts thus brought into contact being supposed to coalesce. By this mode of conception, these anatomists held that the viscera were placed in the same connexion as in the vertebrate type, and the functions exercised in an analogous manner.

To decide on the reality of the analogy thus asserted, clearly belonged to the jurisdiction of the most eminent anatomists and physiologists. The Memoir was committed to Geoffroy Saint-Hilaire and Latreille, two eminent zoologists, in order to be reported on. Their report was extremely favourable; and went almost to the length of adopting the views of the authors.

Cuvier expressed some dissatisfaction with this report on its being read; and a short time afterward, represented Geoffroy Saint-Hilaire as having asserted that the new views of Laurencet and Meyranx refuted completely the notion of the great interval which exists between molluscous and vertebrate animals. Geoffroy protested against such an interpretation of his expressions; but it soon appeared, by the controversial character which the discussions on this and several other subjects assumed, that a real opposition of opinions was in action.

Without attempting to explain the exact views of Geoffroy, (we may, perhaps, venture to say that they are hardly yet generally understood with sufficient distinctness to justify the mere historian of science in attempting such an explanation,) their general tendency may be sufficiently collected from what has been said; and from the phrases in which his views are conveyed. The principle of connexions, the elective affinities of organic elements, the equilibrization of organs,—such are the designations of the leading doctrines which are unfolded in the preliminary discourse of his Anatomical Philosophy. Elective affinities of organic elements are

⁶ Princ. de Phil. Zool, discutes en 1830, p 36. 7 p. 50.
8 Phil. Zool, 15.

the forces by which the vital structures and varied forms of living things are produced; and the principles of connexion and equilibrium of these forces in the various parts of the organization, prescribe limits and conditions to the variety and developement of such forms.

The character and tendency of this philosophy will be, I think, much more clear, if we consider what it excludes and denies. It rejects altogether all conception of a plan and purpose in the organs of animals, as a principle which has determined their forms, or can be of use in directing our reasonings. 'I take care,' mys Geoffroy, 'not to ascribe to God any intention.' And when Cuvier speaks of the combination of organs in such order that they may be in consistence with the part which the animal has to play in nature, his rival rejoins, 10 I 'know nothing of animals which have to play a part in nature.' Such a notion is, he holds, unphilosophical and dangerous. It is an abuse of final causes which makes the cause to be engendered by the effect. And to illustrate still further his own view, he says, 'I have read concerning fishes, that because they live in a medium which resists more than air, their motive forces are calculated so as to give them the power of progression under those circumstances. By this mode of reasoning, you would say of a man who makes use of crutches, that he was originally destined to the misfortune of having a leg paralysed or amputated.

How far this doctrine of unity in the plan in animals is admissible or probable in physiology when kept within proper limits, that is, when not put in opposition to the doctrine of a purpose involved in the plan of animals, I do not pretend even to conjecture. The question is one which appears to be at present deeply occupying the minds of the most learned and profound physiologists; and such persons alone, adding to their knowledge and zeal, judicial sagacity and impartiality, can

^{9 ·} Je me garde de prêter à Dieu aucune intention.' Phil. Zool, 10.

10 · Je ne connais point d'animal qui norve jouer un rôle dans la mature.' p. 65.

tell us what is the general tendency of the best researches on this subject. But when the anatomist expresses such opinions, and defends them by such illustrations as those which I have just quoted. we perceive that he quits the entrenchments of his superior science, in which he might have remained unassatisble so long as the question was a professional one, and the discussion is open to those who possess no pecular knowledge of anatomy. We shall, therefore, venture to say a few words upon it.

Sect. 2 .- Estimate of the Doctrine of Unity of Plan.

It has been so often repeated, and so generally allowed in modern times, that Final Causes ought not to be made our guides in natural philosophy, that a prejudice has been established against the introduction of any views to which this designation can be applied, into physical speculations. Yet, in fact, the assumption of an end or purpose in the structure of organized beings, appears to be an intellectual habit which no efforts can cast off. It has prevailed from the earliest to the latest ages of zoological research; appears to be fastened upon us alike by our ignorance and our knowledge; and has been formally accepted by so many great anatomists, that we cannot feel any scruple in believing the rejection of it to be the superstition of a false philosophy, and a result of the exaggeration of other principles which are supposed capable of superseding its use. And the doctrine of unity of plan of all animals, and the other principles associated with this doctrine, so far as they exclude the conviction of an intelligible scheme

It so far as this doctrine is generally accepted among the best physiologists, we cannot doubt the propriety of Meckel's remarks, (Comparative Anatomy, 1821, Pref. p. xi.) that it cannot be truly asserted either to be new, or to be peculiarly due to Geoffroy Saint-Hilaire.

15 It is hardly worth while an-

awering such illustrations, but I may remark, that the one quoted above, irrelevant and unbecoming as it is, tells altogether against its author. The fact that the wooden leg is of the same length as the other, proves, and would satisfy the most incredulous man, that it was intended for walking.

and a discoverable end, in the organization of animals, appear to be utterly erroneous. I will offer a few reasons for an opinion which may appear presumptuous in a writer who has only a general knowledge of the

subject.

1. In the first place, it appears to me that the argumentation on the case in question, the Sepia, does by no means turn out to the advantage of the new hypothesis. The arguments in support of the hypothetical view of the structure of this mollusc were, that by this view the relative position of the parts was explained. and confirmations which had appeared altogether anomalous, were reduced to rule; for example, the beak, which had been supposed to be in a position the reverse of all other beaks, was shown, by the assumed posture, to have its upper mandible longer than the lower, and thus to be regularly placed 'But,' says Cuvier, 13 'supposing the posture, in order that the side on which the funnel of the sepus is folded should be the back of the animal, considered as similar to a vertebrate, the brain with regard to the beak, and the cesophagus with regard to the liver, should have positions corresponding to those in vertebrates; but the positions of these organs are exactly contrary to the hypothesis. How, then, can you say,' he asks, 'that the cephalopods and vertebrates have identity of composition, unity of composition. without using words in a sense entirely different from their common meaning?'

This argument appears to be exactly of the kind on which the value of the hypothesis must depend.14 It

13 G. S. H Phil. Zool. p. 70. that the back is determined by its ti I do not dwell on other argu- dark colour, or even by its position

ments which were employed. It when the animal is in motion; was given as a circumstance sug- they all know that the badger has gesting the supposed posture of a black belly and a white back ; the type, that in this way the back that an infinity of other automals, was coloured, and the belly was especially among insects, are in white. On this Cuvier observes, the same case, and that many (Phil. Zool. pp. 93, 58.) 'I must fishes swim on their sids or with say, that I do not know any natu- their belly upwards ralist so ignorant as to suppose

is, therefore, interesting to see the reply made to it by the theorist. It is this: 'I admit the facts here stated, but I deny that they lead to the notion of a different sort of animal composition. Molluscous animals had been placed too high in the zoological scale, but if they are only the embryos of its lower stages, if they we only beings in which far fewer organs come into play, it does not follow that the organs are destitute of the relations which the power of successive generations may demand. The organ A will be in an unusual relation with the organ C, if B has not been produced,if a stoppage of the development has fallen upon the latter organ, and has thus prevented its production. And thus,' he says, 'we see how we may have different arrangements, and divers constructions as they appear to the eye.'

It seems to me that such a concession as this entirely destroys the theory which it attempts to defend; for what arrangement does the principle of unity of composition exclude, if it admits unusual, that is, various arrangements of some organs, accompanied by the total absence of others? Or how does this differ from Cuvier's mode of stating the conclusion, except in the introduction of certain arbitrary hypotheses of developement and stoppage ! 'I reduce the facts,' Currer says, 'to their true expression, by saying that cephalopods have several organs which are common to them and vertebrates, and which discharge the same offices: but that these organs are in them differently distributed, and often constructed in a different manner; and they are accompanied by several other organs which vertebrates have not; while these on the other hand have several which are wanting in cephalopoda'

We shall see afterwards the general principles which Cuvier himself considered as the best guides in these reasonings. But I will first add a few words on the disposition of the school now under consideration, to

reject all assumption of an end.

2. That the parts of the bodies of animals are made in order to discharge their respective offices, is a conviction which we cannot believe to be otherwise than n irremovable principle of the philosophy of organization, when we see the manner in which it has constantly forced itself upon the minds of zoologists and matomists in all ages; not only as an inference, but as a guide whose indications they could not help following. I have already noticed expressions of this conviction in some of the principal persons who occur in the history of physiology, as Galen and Harvey. I might add many more, but I will content myself with adducing a contemporary of Geoffroy's, whose testimony is the more remarkable, because he obviously hares with his countryman in the common prejudice against the use of final causes. 'I consider,' he says, in speaking of the provisions for the reproduction of animals, to with the great Bacon, the philosophy of final causes as sterile; but I have elsewhere acknowledged that it was very difficult for the most cautious man never to have recourse to them in his explanations. After the survey which we have had to take of the lastory of physiology, we cannot but see that the assumption of anal causes in this branch of science is so far from being sterile, that it has had a large share in every discovery which is included in the existing mass of real knowledge. The use of every organ has been discovered by starting from the assumpsion that it must have some use. The doctrine of the circulation of the blood was, as we have seen, clearly and professedly due to the persuasion of a purpose in the circulatory apparatus. The study of comparative anatomy is the study of the adaption of animal structures to their purposes. And we shall soon have to how that this conception of final causes has, in our own times, been so far from barren, that it has, in the hands of Cuvier and others, enabled us to become intimately acquainted with vast departments of zoology to which we have no other mode of access. It has placed before us in a complete state, animals, of which, for thousands of years, only a few fragments have existed, and which differ widely from all existing

¹⁴ Cabanis, Rapports du l'hymque et du Morale de l'Homme, 1, 299.

VOL IIL C C

animals; and it has given birth, or at least has given the greatest part of its importance and interest to a science which forms one of the brightest parts of the modern progress of knowledge. It is, therefore, very far from being a vague and empty assertion, when we say that final causes are a real and indestructible element in zoological philosophy, and that the excussion of them, as attempted by the school of which we speak, is a fundamental and most mischievous errour.

3. Thus, though the physiologist may persuade himself that he ought not to refer to final causes, we find that, practically, he cannot help doing this, and that the event shows that his practical habit is right and well-founded. But he may still cling to the speculative difficulties and doubts in which such subjects may be involved by a priori considerations. He may say, as Saint-Hilaire does say, 16 'I ascribe no intention to God, for I mistrust the feeble powers of my reason. I observe facts merely, and go no further. I only pretend to the character of the historian of what is.' 'I cannot make Nature an intelligent being who does nothing in vain, who acts by the shortest mode, who does all for the best,'

I am not going to enter at any length into this subject, which, thus considered, is metaphysical and theological, rather than physiological. If any one maintain, as some have maintained, that no manifestation of means apparently used for ends in nature, can prove the existence of design in the Author of nature, this is not the place to refute such an opinion in the general form. But I think it may be worth while to show, that even those who incline to such an opinion, still cannot resist the necessity which compels men to assume, in organized beings, the existence of an end.

Among the philosophers who have referred our conviction of the being of God to our moral nature, and have denied the possibility of demonstration on mere physical grounds, Kant is perhaps the most

eminent. Yet he has asserted the reality of such a principle of physiology as we are now maintaining in the most emphatic manner. Indeed, this assumption of an end makes his very definition of an organized being. 'An organized product of nature is that in which all the parts are mutually ends and means.'17 And this, he says, is a universal and necessary maxim. He adds, 'It is well known that the anatomizers of plants and animals, in order to investigate their structure, and to obtain an insight into the grounds why and to what end such parts, why such a situation and connexion of the parts, and exactly such an internal form, come before them, assume, as indispensably necessary, this maxim, that in such a creature nothing is in vain, and proceed upon it in the same way in which in general natural philosophy we proceed upon the principle that nothing happens by chance. In fact, they can as little free themselves from this teleological principle as from the general physical one; for as, on omitting the latter, no experience would be possible, so on omitting the former principle, no clue could exist for the observation of a kind of natural objects which can be considered teleologically under the conception of natural ends.'

Even if the reader should not follow the reasoning of this celebrated philosopher, he will still have no difficulty in seeing that he asserts, in the most distinct manner, that which is denied by the author whom we have before quoted, the propriety and necessity of assuming the existence of an end as our guide in the

study of animal organization.

4. It appears to me, therefore, that whether we judge from the arguments, the results, the practice of physiologists, their speculative opinions, or those of the philosophers of a wider field, we are led to the same conviction, that in the organized world we may and must adopt the belief, that organization exists for its purpose, and that the apprehension of the purpose may guide us in seeing the meaning of the organization.

¹⁷ Urtheslakraft, p. 296.

tion. And I now proceed to show how this princip has been brought into additional clearness and use Cuvier.

In doing this, I may, perhaps, be allowed to make reflection of a kind somewhat different from the ceding remarks, though suggested by them. In anot work, 18 I endeavoured to show that those who he been discoverers in science have generally had min the disposition of which was to believe in an intellig Maker of the universe; and that the scientific speci tions which produced an opposite tendency, were get rally those which, though they might deal familia with known physical truths, and conjecture boldly regard to the unknown, did not add to the number solid generalizations. In order to judge whether remark is distinctly applicable in the case now of sidered, I should have to estimate Cuvier in an parison with other physiologists of his time, which do not presume to do. But I may observe, that he allowed by all to have established, on an indestruction basis, many of the most important generalization which zoology now contains; and the principal des which his critics have pointed out, has been, that did not generalize still more widely and boldly. appears, therefore, that he cannot but be placed amount the great discoverers in the studies which he pursue and this being the case, those who look with please on the tendency of the thoughts of the greatest me to an Intelligence far higher than their own, mustgratified to find that he was an example of this 🕍 dency, and that the acknowledgement of a creating purpose, as well as a creative power, not only enter into his belief, but made an indispensable and prom nent part of his philosophy.

¹⁸ Bridgewater Treatise, B. ill e vil. and vili. On Inductive Hell of Thought, and on Deductive Habits of Thought.

Sect. 3.—Establishment and Application of the Principle of the Conditions of Existence of Animals.—
Cuvier.

WE have now to describe more in detail the doctrine which Cuvier maintained in opposition to such opinions we have been speaking of; and which, in his way of pplying it, we look upon as a material advance in hysiological knowledge, and therefore give to it a distinct place in our history. 'Zoology has,' he says,19 the outset of his Règne Animal, 'a principle of easoning which is peculiar to it, and which it employs with advantage on many occasions: this is the principle If the Conditions of Existence, vulgarly called the priniple of Final Causes. As nothing can exist if it do not combine all the conditions which render its existence possible, the different parts of each being must be cotrdinated in such a manner as to render the total being possible, not only in itself, but in its relations to those which surround it; and the analysis of these conditions often leads to general laws, as clearly demonstrated as those which result from calculation or from experience.'

This is the enunciation of his leading principle in general terms. To our ascribing it to him, some may object, on the ground of its being self-evident in its nature, 20 and having been very anciently applied. But to this we reply, that the principle must be considered as a real discovery, in the hands of him who first shows how to make it an instrument of other discoveries. It is true, in other cases as well as in this, that some vague apprehension of true general principles, such as à priori considerations can supply, has long preceded the knowledge of them as real and verified laws. In such a way it was seen, before Newton, that the motions of the planets must result from attraction; and so, before Dufay and Franklin, it was held that electrical actions must result from a

B Rayne An. p. 6.

fluid. Cuvier's merit consisted, not in seeing that in animal cannot exist without combining all the condtions of its existence; but in perceiving that this truth may be taken as a guide in our researches concernat animals;—that the mode of their existence may be collected from one part of their structure, and the applied to interpret or detect another part. He went on the supposition not only that animal forms have some plan, some purpose, but that they have as intelligible plan, a discoverable purpose. ceeded in his investigations like the decipherer of manuscript, who makes out his alphabet from one part of the context, and then applies it to read the rest. The proof that his principle was something very different from an identical proposition, is to be found in the fact, that it enabled him to understand and arrange the structures of animals with unprecedented clearness and completeness of order; and to restore the forms of the extinct animals which are found in the rocks of the earth, in a manner which has been universally assented to as irresistibly convincing These results cannot flow from a trifling or barren principle; and they show us that if we are disposed to form such a judgment of Cuvier's doctrine, it must be because we do not fully apprehend its import.

To illustrate this, we need only quote the statement which he makes, and the uses to which he applies it Thus in the Introduction to his great work on Found Remains, he says, 'Every organized being forms an entire system of its own, all the parts of which mutually correspond, and concur to produce a certain definite purpose by reciprocal reaction, or by combining to the same end. Hence none of these separate parts can change their forms, without a corresponding change in the other parts of the same animal; and consequently each of these parts, taken separately, indicates all the other parts to which it has belonged. Thus, if the viscera of an animal are so organized as only to be fitted for the digestion of recent flesh, it is also requinite that the jaws should be so constructed as to fit them for devouring prey; the claws must be con

bructed for seizing and tearing it in pieces; the teeth or cutting and dividing its flesh; the entire system of he limbs or organs of motion for pursuing and overaking it, and the organs of sense for discovering it at distance. Nature must also have endowed the brain of the animal with instincts sufficient for concealing teelf, and for laying plans to catch its necessary fictims. By such considerations he has been able to reconstruct the whole of many animals of which parts only were given,—a positive result, which shows both the reality and the value of the truth on which

wrought.

A nother great example, equally showing the immense importance of this principle in Cuvier's hands, is the reform which, by means of it, he introduced into the dassification of animals. Here again we may quote he view he himself has given 22 of the character of his own improvements. In studying the physiology of the natural classes of vertebrate animals, he found, he mys, 'in the respective quantity of their respiration, the reason of the quantity of their motion, and consemently of the kind of locomotion. This, again, furnishes the reason for the forms of their skeletons and muscles; and the energy of their senses, and the force of their digestion, are in a necessary proportion the same quantity. Thus a division which had tall then been established, like that of vegetables, only upon observation, was found to rest upon causes appreinble, and applicable to other cases.' Accordingly, he applied this view to invertebrates;—examined the modifications which take place in their organs of irculation, respiration, and sensation; and having islanded the necessary results of these modifications, be deduced from it a new division of those animals, in which they are arranged according to their true valations.

Such have been some of the results of the principle of the Conditions of Existence, as applied by its great essertor.

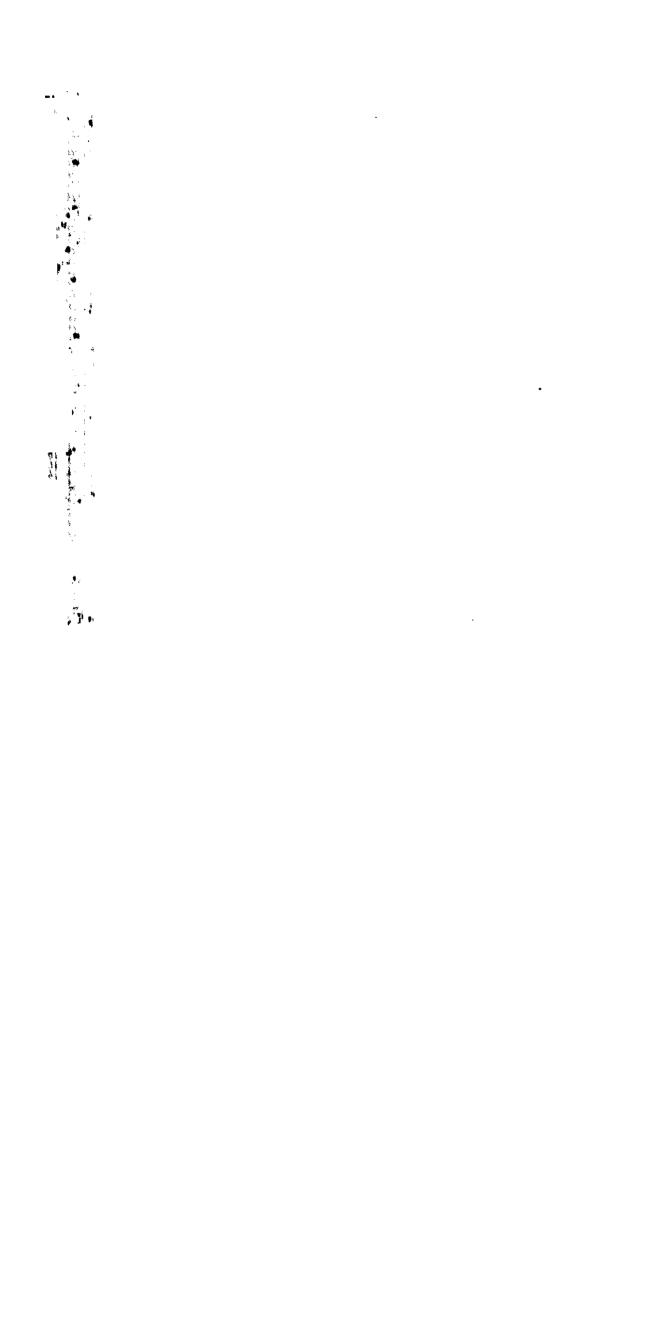

²¹ Theory of the Earth, p. 90.

It is clear, indeed, that such a principle could acquire its practical value only in the hands of person intimately acquainted with anatomical detail with the functions of the organs, and with their variety in different animals. It is only by means of sach nutriment that the embryo truth could be developed into a vast tree of science. But it is not the les clear, that Cuvier's immense knowledge and great powers of thought led to their results, only by being employed under the guidance of this master-principle and, therefore, we may justly consider it as the datinctive feature of his speculations, and follow it with a gratified eye, as the thread of gold which runs through, connects, and enriches his zoological researches: -gives them a deeper interest and a higher value than can belong to any view of the organical sciences, in which the very essence of organization u

kept out of aight.

The real philosopher, who knows that all the kinds of truth are intimately connected, and that all the best hopes and encouragements which are granted to our nature must be consistent with truth, will be satisfied and confirmed, rather than surprized and disturbed, thus to find the Natural Sciences leading him to the borders of a higher region. To him it will appear natural and reasonable, that, after journeying so long among the beautiful and orderly laws by which the universe is governed, we find ourselves at last approaching to a Source of order and law, and intellectual beauty.-that, after venturing into the region of life and feeling and will, we are led to believe the Fountain of life and will, not to be itself unintelligent and dead. but to be a living Mind, a Power which aims as well as acts. To us this doctrine appears like the natural cadence of the tones to which we have so long been listening; and without such a final strain our ears would have been left craving and unsatisfied. We have been lingering long amid the barmonies of lav and symmetry, constancy and development, and these notes, though their music was sweet and deep, must too often have sounded to the ear of our moral nature,

around us, but conveying no definite thought, moulded into no intelligible announcement. But one passage which we have again and again caught by snatches, though sometimes interrupted and lost, at last swells in our ears full, clear, and decided; and the religious 'Hymn in honour of the Creator,' to which Galen so gladly lent his voice, and in which the best physiologists of succeeding times have ever joined, is filled into a richer and deeper harmony by the greatest philosophers of these later days, and will roll on hereafter the 'perpetual song' of the temple of science.

BOOK XVIII.

THE PALETIOLOGICAL SCIENCES.

HISTORY OF GEOLOGY.

Di quibus imperium est animarum, Umbresque silentes, Rt Chaos, et Phlegethon, loca nocte silentia late, Sit mihi fas audita loqui, sit, numine vestro Pandere res alta terra et caligine mersas.

VIRGIL. An. vi 164.

Ye Mighty Ones, who sway the Souls that go Amid the marvels of the world below! Ye, eilent Shades, who sit and hear around! Chaos! and Streams that burn beneath the ground! All, all forgive, if by your converse starred, My lips shall utter what my cars have heard; If shall speak of things of doubtful birth, Deep sunk in darkness, as deep sunk in earth.

INTRODUCTION.

Of the Palætiological Sciences.

WE now approach the last Class of Sciences which we nter into the design of the present work; and of these, Geology is the representative, whose history we shall therefore briefly follow. By the Class of Sciences to which I have referred it, I mean to point out those researches in which the object is, to ascend from the present state of things to a more ancient condition, from which the present is derived by in-

telligible causes.

The sciences which treat of causes have sometimes been termed atiological, from giria, a cause: but this term would not sufficiently describe the speculations of which we now speak, since it might include sciences which treat of Permanent Causality, like Mechanics, as well as inquiries concerning Progressive Causation. The investigations which I now wish to group together, deal, not only with the possible, but with the actual past; and a portion of that science on which we are about to enter, Geology, has properly been termed Palcontology, since it treats of beings which formerly existed. Hence, combining these two notions, Palætiology appears to be a term not inappropriate, to describe those speculations which thus refer to actual past events, and attempt to explain them by laws of causation.

Such speculations are not confined to the world of inert matter; we have examples of them in inquiries concerning the monuments of the art and labour of distant ages; in examinations into the origin and early progress of states and cities, customs, and languages;

Ι Πάλαι, όντα,

as well as in researches concerning the causes and formations of mountains and rocks, the imbedding of fossils in strata, and their elevation from the botton of the ocean. All these speculations are connected by this bond,—that they endeavour to ascend to a ma state of things, by the aid of the evidence of the present. In asserting, with Cuvier, that 'The geolegist is an antiquary of a new order, we do not mark a fanciful and superficial resemblance of employment merely, but a real and philosophical connexion of the principles of investigation. The organic fossils which occur in the rock, and the medals which we find in the ruins of ancient cities, are to be studied in a smile spirit and for a similar purpose. Indeed, it is not always easy to know where the task of the geologist ends, and that of the antiquary begins. The study of ancient geography may involve us in the examination of the causes by which the forms of coasts and plaint is changed; the ancient mound or scarped rock may force upon us the problem, whether its form is the work of nature or of man; the ruined temple mar exhibit the traces of time in its changed level, and seeworn columns; and thus the antiquarian of the earth may be brought into the very middle of the domain belonging to the antiquarian of art.

Such a union of these different kinds of archeological investigations has, in fact, repeatedly occurred The changes which have taken place in the temple of Jupiter Serapis, near Puzzuoli, are of the sort which have just been described; and this is only one example. of a large class of objects, -the monuments of art converted into records of natural events. And on a wider scale, we find Cuvier, in his inquiries into geological changes, bringing together historical and physical Dr. Prichard, in his Researches auto the Physical History of Man, has shown that to execute such a design as his, we must combine the knowledge of the physiological laws of nature with the traditions of history and the philosophical comparison of lan-And even if we refuse to admit, as part of the business of geology, inquiries concerning the origin

and physical history of the present population of the globe; still the geologist is compelled to take an interest in such inquiries, in order to understand matters which rigorously belong to his proper domain; for the ascertained history of the present state of things offers the best means of throwing light upon the causes of past changes. Mr. Lyell quotes Dr. Prichard's book more frequently than any geological work of the tame extent.

Again, we may notice another common circumstance in the studies which we are grouping together as palætiological, diverse as they are in their subjects. In all of them we have the same kind of manifestations of a number of successive changes, each springing out of a preceding state; and in all, the phenomena at each step become more and more complicated, by involving the results of all that has preceded, modified by supervening agencies. The general aspect of all these trains of change is similar, and offers the same features for description. The relics and ruins of the earlier states are preserved, mutilated and dead, in the products of The analogical figures by which we are later times. tempted to express this relation are philosophically true. It is more than a mere fanciful description, to say that in languages, customs, forms of society, political institutions, we see a number of formations superimposed upon one another, each of which is, for the most part, an assemblage of fragments and results of the preceding condition. Though our comparison might be bold, it would be just, if we were to assert, that the English language is a conglomerate of Latin words, bound together in a Saxon cement; the fragments of the Latin being partly portions introduced directly from the parent quarry, with all their sharp edges, and partly pebbles of the same material, obscured and shaped by long rolling in a Norman or some other channel. Thus the study of paletiology in the materials of the earth, is only a type of similar studies with respect to all the elements, which, in the history of the earth's inhabitants, have been constantly undergoing a series of connected changes.

But, wide as is the view which such considerations give us of the class of sciences to which geology belong. they extend still further. 'The science of the change which have taken place in the organic and inorgane kingdoms of nature,' (such is the description which has been given of Geology, by following another set of connexious, be extended beyond the modifications of the surface of our own planet.' For we cannot doubt that some resemblance, of a closer or lover kind, has obtained between the changes and causes of change, on other bodies of the universe, and on our own. The appearances of something of the kind of volcanic action on the surface of the moon, are not to be mistaken. And the inquiries concerning the origin of our planet and of our solar system, inquiries to which Geology irresistibly impels her students, direct us to ask what information the rest of the universe cur supply, bearing upon this subject. It has been thought by some, that we can trace systems, more or less like our solar system, in the process of formation; the nebulous matter, which is at first expansive and attenuated, condensing gradually into suns and planets. Whether this Nebular Hypothesis be tenable or net. I shall not here inquire; but the discussion of such a question would be closely connected with geology, both in its interests and in its methods. If men are ever able to frame a science of the past changes by which the universe has been brought into its present condition. this science will be properly described as Cosmical Palatiology.

These palætiological sciences might properly be called historical, if that term were sufficiently precise: for they are all of the nature of history, being concerned with the succession of events; and the part of history which deals with the past causes of events, is, in fact, a moral palætiology. But the phrase Natural History has so accustomed us to a use of the word history in which we have nothing to do with time, that, if we were to employ the word historical to describe the palætiological

² Lyell, Principles of Geology, p. 1.

retood. The fact is, as Mohs has said, that Natural ary, when systematically treated, rigorously exact all that is historical; for it classes objects by permanent and universal properties, and has ing to do with the narration of particular and diffacts. And this is an inconsistency which we not attempt to rectify.

If palætiological sciences, since they undertake to changes to their causes, assume a certain classifi-

n of the phenomena which change brings forth, knowledge of the operation of the causes of These phenomena, these causes, are very rent, in the branches of knowledge which I have classed together. The natural features of the surface, the works of art, the institutions of ty, the forms of language, taken together, are pubtedly a very wide collection of subjects of plation; and the kinds of causation which apply bem are no less varied. Of the causes of change he inorganic and organic world,—the peculiar ciples of Geology, -we shall hereafter have to As these must be studied by the geologist, so, the manner, the tendencies, instincts, faculties, siples, which direct man to architecture and sculpto civil government, to rational and grammatical and which have determined the circumstances progress in these paths, must be in a great the known to the Palætiologist of Art, of Society, of Language, respectively, in order that he may plate soundly upon his peculiar subject. With matters we shall not here meddle, confining ourin our exemplification of the conditions and creas of such sciences, to the case of Geology.

be journey of survey which we have attempted to burn over the field of human knowledge, although fully directed according to the paths and divisions the physical sciences, has already conducted us to boundaries of physical science, and gives us a spee of the region beyond. In following the historical fulle, we found ourselves led to notice the per-

07. III.

ceptive and active faculties of man; it appeared that there was a ready passage from physiology to parche logy, from physics to metaphysics. In the class of sciences now under notice, we are, at a different point carried from the world of matter to the world thought and feeling,-from things to men. For, we have already said, the science of the causes change includes the productions of Man as well as Nature. The history of the earth, and the history the earth's inhabitants, as collected from phenoment are governed by the same principles. Thus the portion of knowledge which seek to travel back towards origin, whether of inert things or of the works of mag resemble each other. Both of them treat of events connected by the thread of time and causation both we endeavour to learn accurately what the present is, and hence what the past has been. historical sciences in the same sense.

It must be recollected that I am now speaking of history as etiological; —as it investigates causes, and as it does this in a scientific, that is, in a rigorous and systematic, manner. And I may observe here, though I cannot now dwell on the subject, that all setiological sciences will consist of three portions; the Description of the facts and phenomena;—the general Theory the causes of change appropriate to the case;—and the Application of the theory to the facts. Thus, taking Geology for our example, we must have, first Descriptive or Phenomenal Geology; next, the exposition of the general principles by which such phenomena 🗪 be produced, which we may term Geological Dynamics and, lastly, doctrines hence derived, as to what have been the causes of the existing state of things, which we may call Physical Geology.

These three branches of geology may be found frequently or constantly combined in the works of writer on the subject, and it may not always be easy to discriminate exactly what belongs to each subject. * But

⁴ The Wernerians, in distin and designating it as Gregorian gulshing their study from Geology, the knowledge of the earth, appear

DESCRIPTIVE GEOLOGY.

CHAPTER I.

PRELUDE TO SYSTEMATIC DESCRIPTIVE GEOLOGY

Sect. 1 .- Ancient Notices of Geological Facts.

THE recent history of Geology, as to its most important points, is bound up with what is doing at present from day to day; and that portion of the history of the science which belongs to the past, has been amply treated by other writers. I shall, therefore, pass rapidly over the series of events of which this history consists, and shall only attempt to mention what may seem to illustrate and confirm my own view

of its state and principles.

Agreeably to the order already pointed out, I shall notice, in the first place, Phenomenal Geology, or the description of the facts, as distinct from the inquire into their causes. It is manifest that such a merely descriptive kind of knowledge may exist; and it prebably will not be contested, that such knowledge ought to be collected, before we attempt to frame theories concerning the causes of the phenomena. But it not be observed, that we are here speaking of the formation of a science; and that it is not a collection of miscilaneous, unconnected, unarranged knowledge that can be considered as constituting science; but a methodical, coherent, and, as far as possible, complete body of facts. exhibiting fully the condition of the earth, as regards those circumstances which are the subject matter of geological speculation. Such a Descriptive Geology is

As MM. Lyell, Fitton, Conyboure, in our own country

Astronomy necessarily preceded Physical Astronomy, or as Classificatory Botany is a necessary accompaniment to Botanical Physiology. We may observe also that Descriptive Geology, such as we now speak of, is one of the classificatory sciences, like Mineralogy or Botany, and will be found to exhibit some of the features of that class of sciences.

Since, then, our History of Descriptive Geology is to include only systematic and scientific descriptions of the earth or portions of it, we pass over, at once, all the casual and insulated statements of facts, though they may be geological facts, which occur in early writers; such, for instance, as the remark of Herodotus,² that there are shells in the mountains of Egypt; or the general statements which Ovid puts in the mouth of Pythagoras:³

Vidi ego quod fuerat solidissima tellus, Rese fretum; vidi factas ex sequere terras, Et procul a pelago conche acuere marinis.

We may remark here already how generally there are mingled with descriptive notices of such geological facts, speculations concerning their causes. Herodotus refers to the circumstance just quoted, for the purpose of showing that Egypt was formerly a gulf of the sea; and the passage of the Roman poet is part of a series of exemplifications which he gives of the philosophical tenet, that nothing perishes but everything changes. It will be only by constant attention that we shall be able to keep our provinces of geology distinct.

Sect. 2.—Early Descriptions and Collections of Fossils.

Ir we look, as we have proposed to do, for systematic and exact knowledge of geological facts, we find nothing which we can properly adduce till we come to modern times. But when facts such as those already mentioned, (that sea-shells and other marine objects are found imbedded in rocks,) and other circumstances in the structure

of the earth, had attracted considerable attention the exact examination, collection, and record of these cocumstances began to be attempted. Among such steps in Descriptive Geology, we may notice descriptions and pictures of fossils, descriptions of veins and mines collections of organic and morganic fossils, maps of the mineral structure of countries, and finally, the discoveries concerning the superposition of strata, the constancy of their organic contents, their correspondence in different countries, and such great general relations of the materials and features of the earth as have been discovered up to the present time. Without attempting to assign to every important advance in author, I shall briefly exemplify each of the modes of contributing to descriptive geology which I have just enumerated.

The study of organic fossils was first pursued with connexion and system in Italy. The hills which on each side skirt the mountain-range of the Apennines are singularly rich in remains of marine animals. When these remarkable objects drew the attention of thoughtful men, controversies soon arose whether they really were the remains of living creatures, or the productions of some capricious or mysterious power by which the forms of such creatures were mimicked; and again, if the shells were really the spoils of the sea, whether they had been carried to the hills by the deluge of which the Scripture speaks, or whether they indicated revolutions of the earth of a different kind. The earlier works which contain the descriptions of the phenomens have, in almost all instances, by far the greater part of their pages occupied with these speculations; indeed, the facts could not be studied without leading to such inferences, and would not have been collected but for the interest which such reasonings possessed. As one of the first persons who applied a sound and vigorous intellect to these subjects, we may notice the celebrated painter Leonardo da Vinci, whom we have already had to refer to as one of the founders of the modern mechanical sciences. He strenuously asserts the contents of the rocks to be real shells, and maintains the reality of

the changes of the domain of land and sea which these poils of the ocean imply. 'You will tell me,' he says, that nature and the influence of the stars have formed these shelly forms in the mountains; then show me a lace in the mountains where the stars at the present by make shelly forms of different ages, and of different pecies in the same place. And how, with that, will you explain the gravel which is hardened in stages at different heights in the mountains? He then mentions everal other particulars respecting these evidences that the existing mountains were formerly the bed of the sea. Leonardo died in 1519. At present we refer to geological essays like his, only so far as they are descriptive. Going onwards with this view, we may notice Fracastoro, who wrote concerning the petrifictions which were brought to light in the mountains of Verona, when, in 1517, they were excavated for the purpose of repairing the city. Little was done in the way of collection of facts for some time after this. In 1669, Steno, a Dane resident in Italy, put forth his treatise, De Solido intra Solidum naturaliter contento; and the following year, Augustino Scilla, a Sicilian painter, published a Latin epistle, De Corporibus Marinis Landescentibus, illustrated by good engravings of fossil-shells, teeth, and corals.4 After another interval of speculative controversy, we come to Antonio Vallisneri, whose letters, De Corpi Marini che su' Monti i trovano, appeared at Venice in 1721. In these letters he describes the fossils of Monte Bolca, and attempts to trace the extent of the marine deposits of Italy, and to distinguish the most important of the fossils. Similar descriptions and figures were published with reference to our own country at a later period. In 1766, Brander's Fossilia Hantoniensia, or Hampshire

drawings of fossil shells, teeth, by Woodward, and are now in and corals, from which the en- the Woodwardian Museum gravings mentioned in the text Cambridge. were executed, as well as the natural objects from which the

Augustine Scilla's original drawings were made, were bought

Fossils, appeared; containing excellent figures of fossils shells from a part of the south coast of England and similar works came forth in other parts of Europe

However exact might be the descriptions and hand thus produced, they could not give such compete information as the objects themselves, collected and permanently preserved in museums. Vallisher says that having begun to collect fossils for the purpose of forming a grotto, he selected the best, and preserved them 'as a noble diversion for the more curious.' The museum of Calceolarius at Verona contained a celebrated collection of such remains. A copious description of it appeared in 1622. Such collections had been made from an earlier period, and catalogues of thew published. Thus Gessner's work, De Rerum Fossilium, Lapudam et Gemmarum Figuris, (1565.) contains . catalogue of the cabinet of petrifactions collected by John Kentman; many catalogues of the same kind appeared in the seventeenth century, Lhwyd's Lyttophylacii Britannici Iconographia, published at Oxford in 1669, and exhibiting a very ample catalogue of English Fossils contained in the Ashmolean Museum, may be noticed as one of these.

One of the most remarkable occurrences in the progress of descriptive geology in England, was the formation of a geological museum by William Woodward as early as 1695. This collection, formed with great labour, systematically arranged, and carefully entalogued, he bequeathed to the University of Cambridge; founding and endowing at the same time a professorship of the study of geology. The Woodwardian Museum still subsists, a monument of the sagacity with which its author so early saw the importance of such a collection.

Collections and descriptions of fossils, including in the term specimens of minerals of all kinds, as well as organic remains, were frequently made, and especially in places where mining was cultivated; but under such circumstances, they scarcely tended at all to that general

⁶ p. z.

⁷ Parkinson, Organie Remoins, vol. i. p. 20.

PRELUDE TO DESCRIPTIVE GEOLOGY. 409

and complete knowledge of the earth of which we are

now tracing the progress.

In more modern times, collections may be said to be the most important books of the geologist, at least next to the strata themselves. The identifications and armagements of our best geologists, the immense studies of fossil anatomy by Cuvier and others, have been contacted mainly by means of collections of specimens. They are more important in this study than in botany, because specimens which contain important geological information are both more rare and more permanent. Plants, though each individual is perishable, perpetuate and diffuse their kind; while the organic impression a stone, if lost, may never occur in a second instance; but, on the other hand, if it be preserved in the museum, the individual is almost as permanent in this case, as the species in the other.

I shall proceed to notice another mode in which such

information was conveyed.

Sect. 3 .- First Construction of Geological Maps.

DR LISTER, a learned physician, sent to the Royal Society, in 1683, a proposal for maps of soils or minerals; in which he suggested that in the map of England, for example, each soil and its boundaries might be distinguished by colour, or in some other way. Such a mode of expressing and connecting our knowledge of the materials of the earth, was, perhaps, obvious, when the mass of knowledge became considerable. In 1720, Fontenelle, in his observations on a paper of De Reaumur's, which contained an account of a deposit of fossil-shells in Tournine, says, that in order to reason on such cases, we must have a kind of geographical charts, constructed according to the collections of shells found in the earth.' But he justly adds, 'What a quantity of observations, and what time, would it not require to form such maps!"

The execution of such projects required, not merely great labour, but several steps in generalization and

classification, before it could take place. Still such attempts were made. In 1743, was published, A new Philosophico-chorographical Chart of East Kent, invented and delineated by Christopher Packe, M.D.; in which however, the main object is rather to express the course of the valleys than the materials of the country. Guettard formed the project of a mineralogical map of France, and Monnet carried this scheme into effect in 1780,8 by order of the king. In these maps, however, the country is not considered as divided into soils, still less strata; but each part is marked with its predominant mineral only. The spirit of generalization which constitutes the main value of such a work is wanting.

Geological maps belong strictly to Descriptive Geology; they are free from those wide and doubtful speculations which form so large a portion of the earlier geological books. Yet even geological maps cannot be usefully or consistently constructed without considerable steps of classification and generalization. When, in our own time, geologists were become weary of controversies respecting theory, they applied themselve with extraordinary zeal to the construction of straugraphical maps of various countries, flattering themselves that in this way they were merely recording incontestable facts and differences. Nor do I mean to intimate that their facts were doubtful, or their distinctions arbitrary. But still they were facts interpreted, associated, and represented, by means of the classifications and general laws which earlier geologists had established, and thus even Descriptive Goology has been brought into existence as a science by the formation of systems and the discovery of principles. At this we cannot be surprized, when we recollect the many steps which the formation of Classificatory Botany required. We must now notice some of the principal discoveries which tended to the formation of Systematic Descriptive Geology.

CHAPTER II.

FORMATION OF SYSTEMATIC DESCRIPTIVE GEOLOGY.

Sect. 1.—Discovery of the Order and Stratification of the Materials of the Earth.

THAT the substances of which the earth is framed are not scattered and mixed at random, but possess identity and continuity to a considerable extent, Lister was aware, when he proposed his map. But there is, in his suggestions, nothing relating to stratification; nor any order of position, still less of time, assigned to these materials. Woodward, however, appears to have been fully aware of the general law of stratification. On collecting information from all parts, 'the result was,' he says, 'that in time I was abundantly assured that the circumstances of these things in remoter countries were much the same with those of ours here: that the stone, and other terrestrial matter. in France, Flanders, Holland, Spain, Italy, Germany, Denmark, and Sweden, was distinguished into strata or layers, as it is in England; that these strata were divided by parallel fissures; that there were enclosed in the stone and all the other denser kinds of terrestrial matter, great numbers of the shells, and other productions of the sea, in the same manner as in that of this island.'1 So remarkable a truth, thus collected from a copious collection of particulars by a patient induction, was an important step in the science.

These general facts now began to be commonly recognized, and followed into detail. Stukeley the antiquary² (1724), remarked an important feature in the strata of England, that their escarpments, or steepest sides, are turned towards the west and north-west;

Natural Bustory of the Earth, 1723.

² Itinerarium Curiosum, 1724.

and Strachey³ (1719), gave a stratigraphical description of certain coal-mines near Bath.⁴ Michell, appeared Woodwardian Professor at Cambridge in 1762, inscribed this stratified structure of the earth far more distinctly than his predecessors, and pointed out, as the consequence of it, that 'the same kinds of earths stones, and numerals, will appear at the surface of the earth in long parallel slips, parallel to the long ridge of mountains; and so, in fact, we find them.'5

Michell (as appeared by papers of his which were examined after his death) had made himself acquainted with the series of English strata which thus occur from Cambridge to York; that is, from the chalk to the coal. These relations of position required that geological maps, to complete the information they conveyed, should be accompanied by geological Sections, or maginary representations of the order and mode of superpositions, as well as of the superficial extent of the strata, as in more recent times has usually been done. The strata, as we travel from the higher to the lower, come from under each other into view, and this out-cropping, basseting, or by whatever other term it is described, is an important feature in their description.

It was further noticed that these relations of position were combined with other important facts, which impositibly suggested the notion of a relation in time. This, indeed, was implied in all theories of the earth; but observations of the facts most require our notice. Steno is asserted by Humboldt⁶ to be the first who in 1669) distinguished between rocks anterior to the existence of plants and animals upon the globe, containing therefore no organic remains; and rocks superimposed on these, and full of such remains; 'turbuli

maris sedimenta sibi invicem imposita.'

Rouelle is stated, by his pupil Desmarest, to have made some additional and important observations.

³ Phil. Trans 1719, and Observations on Strata, 20 1749.

Fitton, Annals of Philosophy, N. S. vol. i. and ii (1832, 3), p. 157.

Phil. Trans. 1760.

⁶ Essai Géognastique.

'He saw,' it is said, 'that the shells which occur in rocks were not the same in all countries; that certain species occur together, while others do not occur in the same beds; that there is a constant order in the arrangement of these shells, certain species lying in distinct bands '7

Such divisions as these required to be marked by technical names. A distinction was made of l'aucienne terre and la nouvelle terre, to which Rouelle added a travaille intermédiaire. Rouelle died in 1770, having been known by lectures, not by books. Lehman, in 1756, claims for himself the credit of being the first to observe and describe correctly the structure of stratified countries; being ignorant, probably, of the labours of Struckey in England. He divided mountains into three classes ? primitive, which were formed with the world :- those which resulted from a partial destruction of the primitive rocks,—and a third class resulting from local or universal deluges. In 1759, also, Arduine,9 in his Memoirs on the mountains of Padua, Vicenza, and Verona, deduced, from original observations, the distinction of rocks into primary, secondary, and tertiary.

The relations of position and fossils were, from this period, inseparably connected with opinions concerning succession in time. Odoardi remarked, that the strata of the Subapennine hills are unconformable to those of the Apennine, (as Strachey had observed, that the strata above the coal were unconformable to the coal; and his work contained a clear argument respecting the different ages of these two classes of hills. Fuchsel was, in 1762, aware of the distinctness of strata of different ages in Germany. Pallas and Saussure were guided by general views of the same kind in observing the countries which they visited: but, perhaps, the general circulation of such notions was most due to Werner.

Sect. 2.—Systematic Form given to Descriptive Geology.
— Werner.

WERNER expressed the general relations of the strate of the earth by means of classifications which, so far as general applicability is concerned, are extremely imperfect and arbitrary, he promulgated a theory which almost entirely neglected all the facts previously discovered respecting the grouping of fossils, which was founded upon observations made in a very hunted district of Germany,-and which was contradicted even by the facts of this district. Yet the acuteness of his discrimination in the subjects which he studed the generality of the tenets he asserted, and the charm which he threw about his speculations, gave to Geology, or, as he termed it, Geognosy, a popularity and reputation which it had never before possessed. His system asserted certain universal formations, which followed each other in a constant order; - granite the lowest,—then mica-slate and clay-slate; upon these primitive rocks, generally highly inclined, rest other transition strata, -upon these, lie secondary ones, which being more nearly horizontal, are called flotz or dat. The term formation, which we have thus introduced, indicating groups which, by evidence of all kinds of their materials, their position, and their organic contents, - are judged to belong to the same period, implies no small amount of theory. yet this term, from this time forth, is to be looked upon as a term of classification solely, so far as classification can be separately attended to.

Werner's distinctions of strata were for the most part drawn from mineralogical constitution. Doubtless, he could not fail to perceive the great importance of organic fossils. 'I was witness,' says M. de Humboldt, one of his most philosophical followers, 'of the lively satisfaction which he felt when, in 1792, M. De Schiotheim, one of the most distinguished geologists of the school of Freiberg, began to make the relations of fossils to strata the principal object of his studies.'

But Werner and the disciples of his school, even the most enlightened of them, never employed the characters derived from organic remains with the same boldness and perseverance as those who had from the first considered them as the leading phenomena: thus M. de Humboldt expresses doubts which perhaps many other geologists do not feel when, in 1823, he says, Are we justified in concluding that all formations are characterized by particular species? that the fossilshells of the chalk, the muschelkalk, the Jura limestone, and the Alpine limestone, are all different? I think this would be pushing the induction much too far. 12 In Prof. Jameson's Geognosy, which may be taken as a representation of the Wernerian doctrines, organic fossils are in no instance referred to as characters of formations or strata. After the curious and important evidence, contained in organic fossils, which had been brought into view by the labours of Italian, English, and German writers, the promulgation of a system of Descriptive Geology, in which all this evidence was neglected, cannot be considered otherwise than as a retrograde step in science.

Werner maintained the aqueous deposition of all strata above the primitive rocks; even of those trap rocks, to which, from their resemblance to lava and other phenomena, Raspe, Arduino, and others, had already assigned a volcanic origin. The fierce and long controversy between the Vulcanists and Neptunists. which this dogma excited, does not belong to this part of our history; but the discovery of veius of granite penetrating the superincumbent slate, to which the controversy led, was an important event in descriptive geology. Hutton, the author of the theory of igneous causation which was in this country opposed to that of Werner, sought and found this phenomenon in the Grampian hills, in 1785. This supposed verification of his system 'filled him with delight, and called forth such marks of joy and exultation, that the guides who accompanied him were persuaded, says his biographer.13 that he must have discovered a vein of al. at

or gold. 14

Desmarest's examination of Auvergne (1768) showed that there was there an instance of a country which could not even be described without terms implying that the basalt, which covered so large a portion of it, had flowed from the craters of extinct volcanoes. His map of Auvergne was an excellent example of a survey of such a country, thus exhibiting features quite different from those of common stratified countries. 15

The facts connected with metalliferous veins were also objects of Werner's attention. A knowledge of such facts is valuable to the geologist as well as to the miner, although even yet much difficulty after ds ad attempts to theorize concerning them. The facts of this nature have been collected in great abundance is all mining districts, and form a prominent part of the descriptive geology of such districts; as, for example, the Hartz, and Cornwall.

Without further pursuing the history of the knowledge of the inorganic phenomena of the earth, I turn to a still richer department of geology, which is con-

cerned with organic fossils.

Sect. 3.—Application of Organic Remains as a Geological Character.—Smith.

ROUELLE and Odoardi had perceived, as we have seen, that fossils were grouped in bands. but from this general observation to the execution of a survey of a large kingdom, founded upon this principle, would have been a vast stride, even if the author of it had been aware of the doctrines thus asserted by these writers. In fact, however, William Smith executed such a survey of England, with no other guide or help than his own sagacity and perseverance. In his employments as a civil engineer, he noticed the remarkable continuity and constant order of the strate

¹³ Playfair's Works, vol. iv. p. 75. 14 Lyell, i 93

in the neighbourhood of Bath, as discriminated by their fossils, and about the year 1793, he 16 drew up a Tabular View of the strata of that district, which contained the germ of his subsequent discoveries. Finding in the north of England the same strata and associations of strata with which he had become acquainted in the west, he was led to name them and to represent them by means of maps, according to their occurrence over the whole face of England. These maps appeared 17 in 1815, and a work by the same author, entitled The English Strata identified by Organic Remains, came forth later. But the views on which this identification of strata rests, belong to a considerably earlier date; and had not only been acted upon, but freely imparted in conversation many years before.

In the mean time the study of fossils was pursued with zeal in various countries. Lamarck and Defrance employed themselves in determining the fossil shells of the neighbourhood of Paris; 18 and the interest inspired by this subject was strongly nourished and stimulated by the memorable work of Cuvier and Brongniart, On the Environs of Paris, published in 1811, and by Cuvier's subsequent researches on the subjects thus brought under notice. For now, not only the distinction, succession, and arrangement. but many other relations among fossil strata, irresistibly arrested the attention of the philosopher, Brongniart 19 showed that very striking resemblances occurred in their fossil remains, between certain strata of Europe and of North America, and proved that a rock may be so much disguised, that the identity of the stratum can only be recognized by geological characters.20

The Italian geologists had found in their hills, for the most part, the same species of shells which existed

¹⁶ Fitton, p. 148 17 Brit. Assoc 1834 Conybeare, p. 373,

¹⁹ Hat Nat des Crustaces Foseiles, pp. 57. 62.

P Humboldt, Gias. d. R. p. 45.

in their seas but the German and English writers a Gesner, 21 Raspe, 22 and Brander, 23 had perceived that the fossil-shells were either of unknown species or if such as lived in distant latitudes. To decide that up animals and plants, of which we find the remains in a fossil state, were of species now extinct, obviously required an exact and extensive knowledge of natural history. And if this were so, to assign the relations of the past to the existing tribes of beings, and the pecunarities of their vital processes and habite were tasks which could not be performed without the most consummate physiological skill and talent. tasks, however, have been the familiar employments of geologists, and naturalists incited and appealed to by geologists, ever since Cuvier published his examinated of the fossil inhabitants of the Paris basin. Without attempting a history of such labours, I may notice a few circumstances connected with them.

Sect. 4 .- Advances in Palaeontology .- Curier.

So long as the organic fossils which were found in the strata of the earth were the remains of marine animals, it was very difficult for geologists to be assured that the animals were such as did not exist in any part or clime of the existing ocean. But when large land and river animals were discovered, different from any known species, the persuasion that they were of extinct races was forced upon the naturalist. Yet this opinion was not taken up slightly, nor acquiesced in without many struggles.

Bones supposed to belong to fossil elephants, were some of the first with regard to which this conclusion was established. Such remains occur in vast numbers in the soil and gravel of almost every part of the world; especially in Siberia, where they are called the bones of the mammoth. They had been noticed by the ancients, as we learn from Pliny, and had been ascribed to human giants, to elephants imported by

²¹ Lyell, i. 70. 22 1b. 74. 22 1b. 76

the Romans, and to many other origins. But in 1706, Davier had examined these opinions with a more probund knowledge than his predecessors; and he thus cated the result of his researches.25 'With regard to that have been called the fossil remains of elephants. rom Tentzelius to Pallas, I believe that I am in a andition to prove, that they belong to animals which were very clearly different in species from our existing lephants, although they resembled them sufficiently to e considered as belonging to the same genera.' He had anded this conclusion principally on the structure of he teeth, which he found to differ in the Asiatic and African elephant; while, in the fossil animal, it was different from both. But he also reasoned in part on he form of the skull, of which the best-known example had been described in the Philosophical Transactions early as 1737.20 'As soon,' says Cuvier, at a later period, 'as I became acquainted with Messerschmidt's drawing, and joined to the differences which it presented, those which I had myself observed in the inferior jaw and the molar teeth, I no longer doubted that the fossil elephants were of a species different from the Indian elephant. This idea, which I announced to the Institute in the month of January, 1796, opened to me views entirely new respecting the theory of the earth; and determined me to devote myself to the long researches and to the assiduous labours which have now occupied me for twenty-five years. 27

We have here, then, the starting-point of those researches concerning extinct animals, which, ever since that time, have attracted so large a share of notice from geologists and from the world. Cuvier could hardly have anticipated the vast storehouse of materials which lay under his feet, ready to supply him occupation of the most intense interest in the career on which he had thus entered. The examination of the strata

Mém. Inst. Math. et Phys. serschmidt in 1722 Phil. Trans.

Described by Breyne from a "Gesemens Fossiles, second edit."

specimen found in Siberia by Mes- 1 179.

on which Paris stands, and of which its building consist, supplied him with animals, not only liferat from existing ones, but some of them of great are at curious peculiarities. A careful examination of the remains which these strata contain was undertain soon after the period we have referred to. In 1804 Defrance had collected several hundreds of unscribed species of shells, and Lamarck began a sees of Memoirs upon them; remodelling the whole of Conchology, in order that they might be included a its classifications. And two years afterwards (150) appears the first of Cuvier's grand series of Memor containing the restoration of the vertebrate annual d these strata. In this vast natural museum, and it contributions from other parts of the globe, he discovered the most extraordinary creatures .- the Palseotherium. which is intermediate between the horse and the rethe Anoplotherium, which stands nearest to the rhmoceros and the tapir; the Megalonix and Megatherum, animals of the sloth tribe, but of the size of the ox and the rhinoceros. The Memoirs which contained these and many other discoveries, set the naturalists to work in every part of Europe.

Another very curious class of animals was brought to light principally by the geologists of England; animals of which the bones, found in the lias stratum, were at first supposed to be those of crocodiles. But in 1816,30 Sir Everard Home says, 'In truth, on a consideration of this skeleton, we cannot but be inclined to believe, that among the animals destroyed by the catastrophes of remote antiquity, there had been some at least that differ so entirely in their structure from any which now exist as to make it impossible to arrange their fossil remains with any known class of animals.' The animal thus referred to, being clearly intermediate between fishes and lizards, was named by Mr. Konig, Ichthyosaurus; and its structure and con-

²⁸ Annales du Muséum d'Hist. Nat. tom. l. p. 308, and the following volumes.

3 Daubulsson, ii 411.

³⁰ Phil. Trans. 1816, p. 20.

another extinct animal of which he and Mr. de la cohe had collected the remains. This animal, still core nearly approaching the lizard tribe, was by Mr. on the called Plesiosaurus. The call of these two

mera several species were afterwards found.

Before this time, the differences of the races of mimals and plants belonging to the past and the resent periods of the earth's history, had become a ading subject of speculation among geological natu-The science produced by this study of the stural history of former states of the earth has been ermed Palacontology, and there is no branch of human mowledge more fitted to stir men's wonder, or to acite them to the widest physiological speculations, but in the present part of our history this science equires our notice, only so far as it aims at the estoration of the types of ancient animals, on clear and undoubted principles of comparative anatomy. To how how extensive and how conclusive is the science when thus directed, we need only refer to Cuvier's Ossemens Fossiles, 32 a work of vast labour and probund knowledge, which has opened wide the doors of his part of geology. I do not here attempt even to mention the labours of the many other emment contributors to Palæontology; as Brocchi, Des Hayes, Sowerby, Goldfuss, Agassiz, who have employed themselves on animals, and Schlottheim, Brongniart, Hutton, Landley, on plants.

[2nd Ed.] [Among the many valuable contributions to Pakeontology in more recent times, I may especially mention Mr. Owen's Reports on British Fossil Reptiles, on British Fossil Mammalia, and on the Extinct Animals of Australia, with descriptions of certain Fossils indicative of large Marsupial Pachydermata: and M. Agassiz's Report on the Fossil Fishes of the Devonian

³¹ Geol. Trans vol v

The first edition appeared in 1812, consisting principally of the Memoirs to which reference has already been made

System, his Synoptical Table of British Fossil Fish, and his Report on the Fuhes of the London ('lay. All these are contained in the volumes produced by the

British Association from 1839 to 1845.

A new and most important instrument of palaoutological investigation has been put in the geologist shad by Prof. Owen's discovery, that the internal structure of teeth, as disclosed by the microscope, is a mean of determining the kind of the animal. He has carried into every part of the animal kingdom an examination founded upon this discovery, and has published the results of this in his Odontography. As an example of the application of this character of animals, I may mention that a tooth brought from Riga by Sir R. Murchison was in this way ascertained by Mr. Owen to belong to a fish of the genus Dendrodus. (Geology of Russia, 1, 67.)]

When it had thus been established, that the strate of the earth are characterized by innumerable remains of the organized beings which formerly inhabited it, and that anatomical and physiological considerations must be carefully and skilfully applied in order rightly to interpret these characters, the geologist and the palæontologist obviously had, brought before them, many very wide and striking questions. Of these we may give some instances; but, in the first place, we may add a few words concerning those eminent philosophers to whom the science owed the basis on which

succeeding speculations were to be built.

Sect. 5.—Intellectual Characters of the Founders of Systematic Descriptive Geology.

It would be in accordance with the course we have pursued in treating of other subjects, that we should attempt to point out, in the founders of the science now under consideration, those intellectual qualities and habits to which we ascribe their success. The very recent date of the generalizations of geology, which has hardly allowed us time to distinguish the calm expression of the opinion of the wisest judges, might, in this

instance, relieve us from such a duty; but since our plan appears to suggest it, we will, at least, endeavour to mark the characters of the founders of geology, by a

few of their prominent lines.

The three persons who must be looked upon as the main authors of geological classification are, Werner, Smith, and Cuvier. These three men were of very different mental constitution; and it will, perhaps, not be difficult to compare them, in reference to those qualities which we have all along represented as the main features of the discoverer's genius, clearness of ideas, the possession of numerous facts, and the power of bringing these two elements into contact,

In the German, considering him as a geologist, the ideal element predominated. That Werner's powers of external discrimination were extremely acute, we have seen in speaking of him as a mineralogist; and his talent and tendency for classifying were, in his minecalogical studies, fully fed by an abundant store of observation; but when he came to apply this methodizing power to geology, the love of system, so fostered, appears to have been too strong for the collection of facts he had to deal with. As we have already said, he promulgated, as representing the world, a scheme collected from a province, and even too hastily gathered from that narrow field. Yet his intense spirit of method in some measure compensated for other deficiencies, and enabled him to give the character of a science to what had been before a collection of miscellaneous phenomena. The ardour of system-making produced a sort of fusion, which, however superficial, served to bind together the mass of incoherent and mixed materials, and thus to form, though by strange and anomalous means, a structure of no small strength and durability, like the ancient vitrified structures which we find in some of our mountain regions.

Of a very different temper and character was William No literary cultivation of his youth awoke in him the speculative love of symmetry and system, but a aingular clearness and precision of the classifying power, which he possessed as a native talent, was exer-

cised and developed by exactly those geological facts among which his philosophical task lay. Some of the advances which he made, had, as we have seen, been least entered upon by others who preceded hun but of all this he was ignorant; and, perhaps, went on more steadily and eagerly to work out his own ideas, from the persuasion that they were entirely his own. At a later period of his life, he himself published an account of the views which had animated him in his earlier progress. In this account 33 he dates his attempts to discriminate and connect strata from the year 1790, at which time he was twenty years old. In 1792, h 'had considered how he could best represent the order of superposition—continuity of course—and general eastern declination of the strata.' Soon after, doubts which had arisen were removed by the 'discovery of a mode of identifying the strata by the organized fossils respectively imbedded therein. And thus stored with ideas,' as he expresses himself, he began to communicate them to his friends. In all this, we see great vividness of thought and activity of mind unfolding itself exactly in proportion to the facts with which it had to deal. We are reminded of that cyclopean architecture in which each stone, as tt occurs, is, with wonderful ingenuity, and with the least possible alteration of its form, shaped so as to fit its place in a solid and lasting edifice

Different yet again was the character (as a geological discoverer) of the great naturalist of the beginning of the nineteenth century. In that part of his labour of which we have now to speak, Cuvier's dominant ideas were rather physiological than geological. In his views of past physical changes, he did not seek to include any ranges of facts which lay much beyond the narrow field of the Paris basin. But his sagarity in applying his own great principle of the Conditions of Existence, gave him a peculiar and unparalleled power in interpreting the most imperfect fossil records of extinct anatomy. In the constitution of his mind,

⁵ Phic. Mag. 1833, vol. i. p. 38.

all philosophical endowments were so admirably developed and disciplined, that it was difficult to say, whether more of his power was due to genius or to The talent of classifying which he exercised in geology, was the result of the most complete knowledge and skill in zoology; while his views concerning the revolutions which had taken place in the organic and inorganic world, were in no small degree aided by an extraordinary command of historical and other literature. His guiding ideas had been formed, his facts had been studied, by the assistance of all the sciences which could be made to bear upon them. his geological labours we seem to see some beautiful temple, not only firm and fair in itself, but decorated with sculpture and painting, and rich in all that art and labour, memory and imagination, can contribute to its beauty.

[2nd Ed.] (Sir Charles Lyell (B. i. c. iv.) has quoted with approval what I have elsewhere said, that the advancement of three of the main divisions of geology in the beginning of the present century was promoted principally by the three great nations of Europe,—the German, the English, and the French:—Mineralogical Geology by the German school of Werner;—Secondary Geology by Smith and his English successors,—Tertiary Geology by Cuvier and his fellow-labourers in

France.]

CHAPTER III.

Sequel to the Formation of Systematic Descriptive Geology.

Sect. 1.—Reception and Diffusion of Systematical Geology.

IF our nearness to the time of the discoveries to we have just referred, embarrasses us in speciof their authors, it makes it still more difficult to not the reception with which these discoveries methere we may notice a few facts which may not be wout their interest.

The impression which Werner made upon his her was very strong; and, as we have already said, disc were gathered to his school from every country, then went forth into all parts of the world, anim by the views which they had caught from him. may say of him, as has been so wisely said of a pl sopher of a very different kind,1 . He owed his inflato various causes; at the head of which may be pl that genius for system, which, though it cramps growth of knowledge, perhaps finally atones for 🛊 mischief by the zeal and activity which it rouses are followers and opponents, who discover truth by accid when in pursuit of weapons for their warfare.' list of Werner's pupils for a considerable period cluded most of the principal geologists of Europe Freisleben, Mohs, Esmark, d'Andrada, Raumer, E hart, Charpentier, Brocchi. Alexander von Humb and Leopold von Buch went forth from his school observe America and Siberia, the isles of the Atia and the coast of Norway. Professor Jameson blished at Edinburgh a Wernerian Society; and lecture-room became a second center of Werne

¹ Mackintosh on Hobbes, Dissert. p. 177.

between these we may mention as one of the lost distinguished, M. Ami Boué, though, like several thers, he soon cast away the peculiar opinions of the Vernerian school. The classifications of this school ere, however, diffused over the civilized world with attraordinary success; and were looked upon with rent respect, till the study of organic fossils threw them ato the shade.

Smith, on the other hand, long pursued his own houghts without aid and without sympathy. About 700, he became acquainted with a few gentlemen (Dr. Anderson, Mr Richardson, Mr. Townsend, and Mr. Davies,) who had already given some attention to regamic fossils, and who were astonished to find his nowledge so much more exact and extensive than heir own. From this time he conceived the intention publishing his discoveries; but the want of literary sisure and habits long prevented him. His knowledge was orally communicated without reserve to many persons; and thus gradually and insensibly became part of the public stock. When this diffusion of his views had gone on for some time, his friends began to complain that the author of them was deprived of his well-merited share of fame. His delay in publication made it difficult to remedy this wrong; for soon after he published his Geological Map of England, another appeared, founded upon separate observations; and hough, perhaps, not quite independent of his, yet in many respects much more detailed and correct. Thus, though his general ideas obtained universal currency, he did not assume his due prominence as a geologist. In 1818, a generous attempt was made to direct a proper degree of public gratitude to him, in an article a the Edinburgh Review, the production of Dr. Fitton, distinguished English geologist. And when the minent philosopher, Wollaston, had bequeathed to the Geological Society of London a fund from which a gold medal was to be awarded to geological services, the first of such medals was, in 1831, 'given to Mr. William Smith, in consideration of his being a great original

discoverer in English geology; and especially for he having been the first in this country to discover at to teach the identification of strata, and to determine their succession by means of their imbedded fossils.

Cuvier's discoveries, on the other hand, both from the high philosophic fame of their author, and from their intrinsic importance, arrested at once the attention of scientific Europe; and, notwithstanding the undoubted priority of Sunth's labours, for a long time were looked upon as the starting point of our knowledge of organic fossils. And, in reality, although Cuvier's memoirs derived the greatest part of their value from his zoological conclusions, they reflected back no small portion of interest on the classifications of strata, which were involved in his inferences. And the views which he presented gave to geology an attractive and striking character, and a connexion with large physiological as well as physical principles, which added incomparably to its dignity and charm.

In tracing the reception and diffusion of doctrines such as those of Smith and Cuvier, we ought not to omit to notice more especially the formation and history of the Geological Society of London, just mentioned. It was established in 1807, with a view to multiply and record observations, and patiently to await the result at some future period; that is, its founders resolved to apply themselves to Descriptive Geology, thinking the time not come for that theoretical geology which had then long fired the controversial ardour of Neptunists and Plutonists. The first volume of the Transactions of this society was published in 1811. The greater part of the contents of this volume 2 savour of the notions of the Wernerian school; and there are papers on some of the districts in England most rich in fossils, which, Mr. Conybeare says, well exhibit the low state of secondary geology at that period. But a paper by Mr. Parkinson refers to the discoveries both of Smith and of Cuvier; and in the next volume, Mr. Webster gives an account of the Isle of Wight,

Conybeare, Report, Brit. Assoc p. 57a.

following the admirable model of Cuvier and Brongniart's account of the Paris basin. 'If we compare this memoir of Mr. Webster with the preceding one of Dr. Berger, (also on the Isle of Wight,) they at once show themselves to belong to two very distinct eras of science, and it is difficult to believe that the interval which elapsed between their respective publication was

only three or four years.'3

Among the events belonging to the diffusion of sound geological views in this country, we may notice the publication of a little volume entitled, The Geology of England and Wales, by Mr. Conybeare and Mr. Phillips, in 1821, an event far more important than, from the modest form and character of the work, it might at first sight appear. By describing in detail the geological structure and circumstances of one part of England, (at least as far downwards as the coal,) it enabled a very wide class of readers to understand and verify the classifications which geology had then very recently established; while the extensive knowledge and philosophical spirit of Mr. Conybeare rendered it, under the guise of a topographical enumeration, in reality a profound and instructive scientific treatise. The vast impulse which it gave to the study of sound descriptive geology was felt and acknowledged in other countries, as well as in Britain.

Since that period, Descriptive Geology in England has constantly advanced. The advance has been due mainly to the labours of the members of the Geological Society; on whose merits as cultivators of their science, none but those who are themselves masters of the subject, have a right to dwell. Yet some parts of the scientific character of these men may be appreciated by the general speculator; for they have shown that there are no talents and no endowments which may not find their fitting employment in this science. Besides that they have united laborious research and comprehensive views, acuteness and learning, zeal and knowledge, the philosophical eloquence with which

Conybearc, Report, p. 374.

they have conducted their discussions has had a most beneficial influence on the tone of their speculations and their researches in the field, which have carned them into every country and every class of society, have given them that prompt and liberal spirit, and that open and cordial bearing, which results from intercourse with the world on a large and unfettered scale. It is not too much to say, that in our time Practical Geology has been one of the best schools of philosophical and general culture of mind.

Sect. 2. - Application of Systematic Geology. Geological Surveys and Maps.

SUCH surveys as that which Conybeare and Phillips's book presented with respect to England, were not only a means of disseminating the knowledge implied in the classifications of such a work, but they were also an essential part of the Application and Extension of the principles established by the founders of Systematic Geology. As soon as the truth of such a system was generally acknowledged, the persuasion of the property of geological surveys and maps of each country could

not but impress itself on men's minds.

When the earlier writers, as Lister and Fontenelle, spoke of mineralogical and fossilological maps, they could hardly be said to know the meaning of the terms which they thus used. But when subsequent classifications had shown how such a suggestion might be carried into effect, and to what important consequences it might lead, the task was undertaken in various countries in a vigorous and consistent manner. In England, besides Smith's map, another, drawn up by Mr Greenough, was published by the Geological Society in 1819; and, being founded on very numerous observations of the author and his friends, made with great labour and cost, was not only an important correction and confirmation of Smith's labours, but a valuable storehouse and standard of what had then been done in English geology. Leopold von Buch had constructed a geological map of a large portion of Germany, about the same period; but, aware of the difficulty of the task he had thus attempted, he still forbore to publish it. At a later period, and as materials ocumulated, more detailed maps of parts of Germany were produced by Hoffmann and others. The French covernment entrusted to a distinguished Professor of he School of Mines, (M. Brochant de Villiers,) the task of constructing a map of France on the model of Mr. Greenough's; associating with him two younger persons, selected for their energy and talents, MM. de Beaumont and Dufrénoy. We shall have occasion hereafter to speak of the execution of this survey. By various persons, geological maps of almost every country and province of Europe, and of many parts of Asia and America, have been published. I need not enumerate these, but I may refer to the account given of them by Mr. Conybeare, in the Reports of the British Association for 1832, p. 384. These various essays may be considered as contributions, though hitherto undoubtedly very imperfect ones, to that at which Descriptive Geology ought to aim, and which is requisite as a foundation for sound theory; -a complete geological survey of the whole earth. But we must may a few words respecting the language in which such a survey must be written.

As we have already said, that condition which made such maps and the accompanying descriptions possible, was that the strata and their contents had previously undergone classification and arrangement at the hands of the fathers of geology. Classification, in this as in other cases, implied names which should give to the classes distinctness and permanence; and when the series of strata belonging to one country were referred to in the description of another, in which they appeared, as was usually the case, under an aspect at least somewhat different, the supposed identification required a peculiar study of each case, and thus Geology had arrived at the point, which we have before had to notice as one of the stages of the progress of Classificatory Botany, at which a technical nomenclature and a well-understood synonymy were essential parts of the

science.

Sect. 3. -Geological Nomenclature.

By Nomenclature we mean a system of names, and hence we cannot speak of a Geological Nomenclature till we come to Werner and Smith. The earlier manralogists had employed names, often artificial and arbitrary, for special minerals, but no technical and constant names for strata. The elements of Werner's names for the members of his geological series were words in use among minera, as Gneiss, Grames & Thousehiefer, Rothe todte liegende, Zechstein, or arhetrary names of the mineralogists, as Syenite, Serpentine, Porphyry, Grante. But the more technical part of his phraseology was taken from that which is the worst kind of name, arbitrary numeration. Thus he had his first sandstone formation, second sandstone, third sandstone, first flotz limestone, second flotz limestone, third flotz limestone. Such names are, beyond all others, hable to mistake in their application, and likely to be expelled by the progress of knowledge; and accordingly, though the Werneman names for rocks mineralogically distinguished, have still some currency, his sandstones and limestones, after creating endless confusion while his authority had any sway, have utterly disappeared from good geological works.

The nomenclature of Smith was founded upon Eaglish provincial terms of very barbarous aspect, as Cornbrash, Lian, Gault, Clunch Clay, Coral Rag. Yet these terms were widely diffused when his classification was generally accepted; they kept their place, precisely because they had no systematic signification; and many of them are at present part of the geological language

of the whole civilized world.

Another kind of names which has been very prevalent among geologists are those borrowed from place. Thus the Wernerians spoke of Alpine Limestone and Jura Limestone, the English, of Kummerudge Clay and Oxford Clay, Purbeck Marble, and Portland Rock. These names, referring to the stratum of a known locality as a type, were good, as far as an identity with that type had been traced; but when this had been

impletely done, they were liable to great ambiguity.

The Alps or the Jura contain several formations of tone, such terms as we have noticed, borrowed those mountains, cease to be necessarily definite,

may give rise to much confusion.

Ascriptive names, although they might be supposed the best, have, in fact, rarely been fortunate. reason of this is obvious;—the mark which has selected for description may easily fail to be intial, and the obvious connexions of natural facts v overleap the arbitrary definition. As we have ady stated in the history of botany, the establishof descriptive marks of real classes presupposes important but difficult step, of the discovery of marks. Hence those descriptive names only have really useful in geology which have been used out any scrupulous regard to the appropriateness the description. The Green Sand may be white, n, or red; the Mountain Limestone may occur in valleys; the Oohte may have no roe-like strucand yet these may be excellent geological names, hay be applied to formations geologically identical those which the phrases originally designated. The ification may assist the memory, but must not be wed to subjugate the faculty of natural classification. the terms which have been formed by geologists in ent times have been drawn from sources similar to of the older ones, and will have their fortune mined by the same conditions. Thus Mr. Lyell given to the divisions of the tertiary strata the plations Pleiocene, Meiocene, Eucene, accordingly as contain a majority of recent species of shells, a prity of such species, or a small proportion of living cies, which may be looked upon as indicating the of the existing state of the animate creation. in this case, he wisely treats his distinctions, not definitions, but as the marks of natural groups. m plurality of species indicated by the name pleiomust not,' he says,4 ' be understood to imply an

absolute majority of recent fossil shells in all cases, but a comparative preponderance wherever the pleiocen are contrasted with strata of the period immediately

preceding '

Mr. Lyell might have added, that no precise par centage of recent species, nor any numerical criterion whatever, can be allowed to overbear the closer natural relations of strata, proved by evidence of a superor kind, if such can be found. And this would be the proper answer to the objection made by Mr. Deb Beche to these names; namely, that it may happen that the meiocene rocks of one country may be of the same date as the pleiocene of another; the same formstion having in one place a majority, in another, a minority of existing species. We are not to run into this incongruity, for we are not so to apply the names. The formation which has been called pleiocene, must continue to be so called, even where the majority of recent species fails; and all rocks that agree with that in date, without further reference to the numerical relations of their fossils, must also share in the name

To invent good names for these large divisions of the series of strata is indeed extremely difficult. The term Oolite is an instance in which a descriptive word has become permanent in a case of this kind, and, in imitation of it, Pacilite (from ποικίλος, various,) has been proposed by Mr. Conybeare as a name for the group of strata inferior to the colites, of which the Variegated Sandstone (Bunter Sandstein, Grès Bigarri,) is a conspicuous member. For the series of formations which hes immediately over the rocks in which no organic remains are found, the term Transition was long used, but with extreme ambiguity and vagueness. When this series, or rather the upper part of it, was well examined in South Wales, where it consists of many well-marked members, and may be probably taken as a type for a large portion of the rest of the world, it became necessary to give to the group thus explored a name not necessarily leading to assumption

⁵ Report, p. 179.

controversy. Mr. Murchison selected the term fion, borrowed from the former inhabitants of the cary in which his types were found; and this is a excellent in many respects; but one which will ably not quite supersede 'Transition,' because, in places, transition rocks occur which correspond to of the members of the Silveign region.

one of the members of the Silurian region. lough new names are inevitable accompaniments w views of classification, and though, therefore, reological discoverer must be allowed a right to them, this is a privilege which, for the sake of own credit, and the circulation of his tokens, he exercise with great temperance and judgment. Brongniart may be taken as an example of the net of this caution. Acting upon the principle, in a sound one, that inconveniences arise from prical terms which have a mineralogical significahe has given an entirely new list of names of the thers of the geological series. Thus the primitive ratified rocks are terrains agalysiens; the transisemi-compact are hemilysiens; the sedimentary are yzemiens; the diluvial deposits are clys-: and these divisions are subdivided by designas equally novel; thus of the 'terrains yzemiens,' bers are—the terrains clastiques, tritoniens, proes, palæotheriens, epilymniques, thalassiques. Such menclature appears to labour under great inconsnoes, since the terms are descriptive in their vation yet are not generally intelligible, and refer soretical views yet have not the recommendation internatic connexion.

4.—Geological Synonymy, or Determination of Geological Equivalents.

rill easily be supposed that with so many different tes of names as we have mentioned, the same turn may be called by different designations; and a synonymy may be necessary for geology; as it

[·] Brongniaet, Indiente des Terrains, 1829.

was for botany in the time of Banhin, when the plants had been spoken of by so many different appear tions in different authors. But in reality, the sym nymy of geology is a still more important part of subject than the analogy of botany would lead me For in plants, the species are really fire and easily known when seen; and the ambiguity only in the imperfect communication or confused ida of the observers. But in geology, the identity of stratum or formation in different places, though 📷 an arbitrary, may be a very doubtful matter, even to him who has seen and examined. To assign its right character and place to a stratum in a new country, in a great degree, to establish the whole geological history of the country. To assume that the access names may rightly be applied to the strata of different countries, is to take for granted, not indeed the West nerian dogma of universal formations, but a consider able degree of generality and uniformity in the known formations. And how far this generality and unformity prevail, observation alone can teach. The search for geological synonyms in different countries brings before us two questions;—first, are there such synonyms? and only in the second place, and as far as they occur, what are they?

In fact, it is found that although formations which must be considered as geologically identical (because otherwise no classification is possible,) do extend over large regions, and pass from country to country, their identity includes certain modifications; and the determination of the identity and of the modifications are inseparably involved with each other, and almost necessarily entangled with theoretical considerations. And in two countries, in which we find this modified coincidence, instead of saying that the strata are identical and that their designations are synonyms, we may with more propriety, consider them as two corresponding series; of which the members of the one may be treated as the Representatives or Equivalents of the members of the other.

This doctrine of Representatives or Equivalent

apposes that the geological phenomena in the two countries have been the results of similar series of events, which have, in some measure, coincided in time and order; and thus, as we have said, refers us to a theory. But yet, considered merely as a step in classiscation, the comparison of the geological series of strata in different countries is, in the highest degree, important and interesting. Indeed, in the same manner in which the separation of Classificatory from Chemical Mineralogy is necessary for the completion of mineralogical science, the comparative Classification of the strata of different countries according to their resemblances and differences alone, is requisite as a basis for a Theory of their causes. But, as will easily be imagined from its nature, this part of descriptive geology deals with the most difficult and the most elevated problems; and requires a rare union of laborious observation with a comprehensive spirit of philosophical classification.

In order to give instances of this process (for of the vast labour and great talents which have been thus employed in England, France, and Germany, it is only instances that we can give,) I may refer to the geological survey of France, which was executed, as we have already stated, by order of the government. In this andertaking it was intended to obtain a knowledge of the whole mineral structure of France; but no small portion of this knowledge was brought into view, when synonymy had been established between the Secondary Rocks of France and the corresponding members of the English and German series, which had been so well studied as to have become classical points of standard reference. For the purpose of doing this, the principal directors of the survey, MM. Brochant de Villiers, De Beaumont, and Dufrénoy, came to England in 1822, and following the steps of the best English geologists, in a few months made themselves acquainted with the English series. They then returned to France, and, starting from the chalk of Paris in various directions, travelled on the lines which carried them over the edges of the strata which emerge from beneath the chalk, identifying, as they could, the strata with their foreign analogues. They thus recognized almost all the principal beds of the colitic series of England At the same time they found differences as well Thus the Portland and Kimmers resemblances. beds of France were found to contain in abundant a certain shell, the gryphera virgula, which had before been much remarked in those beds in England With regard to the synonyms in Germany, on the other hand, a difference of opinion arose between M. Elie de Beaumont and M. Voltz, the former of sidering the Grès de Vosges as the equivalent of Rothe todte liegende, which occurs beneath the Zan stein, while M Voltz held that it was the lower portion of the Red or Variegated Sandstone which rests on the Zechstein.

In the same manner, from the first promulgation the Wernerian system, attempts were made to identify the English with the German members of the geological alphabet; but it was long before this alphabet we rightly read. Thus the English geologists who first tried to apply the Wernerian series to this countri conceived the Old and New Red Sandstone of England to be the same with the Old and New Red Sandston of Werner; whereas Werner's Old Red, the Rothe tod liegende, is above the coal, while the English Old Re is below it. This mustake led to a further erroncol identification of our Mountain Limestone with Werney First Flotz Limestone; and caused an almost income tricable confusion, which, even at a recent period, be perplexed the views of German geologists respecting this country. Again, the Lias of England was, at find supposed to be the equivalent of the Muschelkalk Germany. But the errour of this identification brought into view by examinations and discussions. which MM. Œvenhausen and Dechen took the less and at a later period, Professor Sedgwick, by a laboriou examination of the strata of England, was enabled show the true relation of this part of the geology the two countries. According to him, the New Re-

⁷ De la Beche, Manual, 305.

considered as one great complex formation, may be divided into seven members, composed of sandstones, limestones, and marls; five of which represent respectively the Rothe todie liegende; the Kupfer schiefer; the Zechstein, (with the Rauchwacké, Asche, and Stinkstein of the Thuringenwald;) the Bunter sandstein, and the Keuper: while the Muschelkulk, which lies between the two last members of the German list, has not yet been discovered in our geological series. 'Such a coincidence,' he observes,' in the subdivisions of two distant mechanical deposits, even upon the supposition of their being strictly contemporaneous, is truly astonishing. It has not been assumed hypothetically, but is the fair result of the

facts which are recorded in this paper.'

As an example in which the study of geological equivalents becomes still more difficult, we may notice the attempts to refer the strata of the Alps to those of the north-west of Europe. The dark-coloured marbles and schists resembling mica slate were, during the prevalence of the Wernerian theory, referred, as was natural, to the transition class. The striking physical characters of this mountain region, and its long-standing celebrity as a subject of mineralogical examination, made a complete subversion of the received opinion respecting its place in the geological series, an event of great importance in the history of the science. Yet this was what occurred when Dr. Buckland, in 1820, threw his piercing glance upon this district. He immedistely pointed out that these masses, by their fossils, approach to the Colitic Series of this country. From this view it followed, that the geological equivalents of that series were to be found among rocks in which the mineralogical characters were altogether different, and that the loose limestones of England represent some of the highly-compact and crystalline marbles of Italy and Greece. This view was confirmed by subsequent investigations; and the correspondence was traced, not only in the general body of the formations, but in the

Gaol. Trans. Second Series, ili. 123. 10 De la Beche, Manual, 313.

occurrence of the Red Marl at its bottom, and

Green Sand and Chalk at its top.

The talents and the knowledge which such trequire are of no ordinary kind; nor, even with a summate acquaintance with the well-ascertained mations, can the place of problematical strata be decided without immense labour. Thus the examination delineation of hundreds of shells by the most absolute conchologists, has been thought necessary in order determine whether the calcareous beds of Maestrand of Gosau are or are not intermediate, as to the organic contents, between the chalk and the terminations. And scarcely any point of geological classification can be settled without a similar union the accomplished naturalist with the laborious geological complished naturalist with the laborious geological complex to the complex to the

gical collector.

It follows from the views already presented, of the part of geology, that no attempt to apply to dist countries the names by which the well-known Europe strata have been described, can be of any value, if 🗈 accompanied by a corresponding attempt to show far the European series is really applicable. This mi be borne in mind in estimating the import of the logical accounts which have been given of various particles. of Asia, Africa, and America. For instance, when I carboniferous group and the new red sandstone etated to be found in India, we require to be assuthat these formations are, in some way, the equilents of their synonyms in countries better explore Till this is done, the results of observation in a places would be better conveyed by a nomenclate implying only those facts of resemblance, differen and order, which have been ascertained in the coun so described. We know that serious errours incurred by the attempts made to identify the Tertistrata of other countries with those first studied in Paris basin. Fancied points of resemblance, Mr. Ly observes, were magnified into undue importance, essential differences in mineral character and organic contents were slurred over.

[2nd Ed.] [The extension of geological surveys,

construction of geological maps, and the determination of the geological equivalents which replace each other in various countries, have been carried on in continuation of the labours mentioned above, with enlarged activity, range, and means. It is estimated that one-third of the land of each hemisphere has been geologically explored; and that thus Descriptive Geology has now been prosecuted so far, that it is not likely that even the extension of it to the whole globe would give any material novelty of aspect to Theoretical Geology. The recent literature of the subject is so voluminous that it is impossible for me to give any account of it here; very imperfectly acquainted, as I am, even with the English portion, and still more, with what has been produced in other countries.

While I admire the energetic and enlightened labours by which the philosophers of France, Belgium, Germany, Italy, Russia, and America, have promoted scientific geology, I may be allowed to rejoice to see in the very phraseology of the subject, the evidence that English geologists have not failed to contribute their share to the latest advances in the science. The following order of strata proceeding upwards is now, I think, recognized throughout Europe. The Silurian; the Devonian, (Old Red Sandstone;) the Carboniferous; the Permian, (Lower part of the new Red Sandstone peries;) the Trias, (Upper three members of the New Red Sandstone series;) the Lias; the Oolite, (in which are reckoned by M. D'Orbigny the Etages Bathonien, Oxomen, Kimmeridgien, and Portlandien;) the Neocomien, (Lower Green Sand,) the Chalk; and above these, Tertiary and Supra-Tertiary beds. Of these, the Silurian, described by Sir R. Murchison from its types in South Wales, has been traced by European Geologiste through the Ardennes, Servia, Turkey, the shores of the gulf of Finland, the valley of the Mississippi, the west coast of North America, and the mountains of South America. Again, the labours of Prof. Sedgwick and Sir R. Murchison, in 1836, 7, and 8, aided by the sagacity of Mr. Lonsdale, led to their placing certain rocks of Devon and Cornwall as a formation intermediate between the Silurian and Carboniferous Server, and the Deconion System thus established has been accepted by geologists in general, and has been traced not only in various parts of Europe, but in Australa and Tasmania, and in the neighbourhood of the Alle-

ghanies.

Above the Carboniferous Series, Sir R. Murchsmand his fellow-labourers, M. de Verneuil and Count Keyserling, have found in Russia a well-developed series of rocks occupying the ancient kingdom of Permia, which they have hence called the Permian formation; and this term also has found general acceptance. The next group, the Keuper, Muschelkalk, and Bunter Sandstein of Germany, has been termed Trics by the continental geologists. The Neocomies is so called from Neuchatel, where it is largely developed Below all these rocks come, in England, the Cambran, on which Prof. Sedgwick has expended so many years of valuable labour. The comparison of the Protozoic and Hypozoic rocks of different countries is probably still incomplete.

To. Miles

The geologists of North America have made great progress in decyphering and describing the structure of their own country; and they have wisely gone, in a great measure, upon the plan which I have commended at the end of the third Chapter,—they have compared the rocks of their own country with each other, and given to the different beds and formations names borrowed from their own localities. This course will facilitate rather than impede the reduction of their classification to its synonyms and equivalents in the old

world.

Of course it is not to be expected nor desired that books belonging to Descriptive Geology shall exclude the other two branches of the subject, Geological Dynamics and Physical Geology. On the contrary, among the most valuable contributions to both these departments have been speculations appended to descriptive works. And this is naturally and rightly more and more the case as the description embraces a wider field. The noble work On the Geology of Russia

SEQUEL TO SYSTEMATIC GEOLOGY. 443

and the Urals, by Sir Roderick Murchison and his companions, is a great example of this, as of other merits in a geological book. The author introduces into his pages the various portions of geological dynamics of which I shall have to speak afterwards; and thus endeavours to make out the physical history of the region, the boundaries of its raised sea bottoms, the shores of the great continent on which the mammoths hived, the period when the gold ore was formed, and when the watershed of the Ural chain was elevated.]

CHAPTER IV.

ATTEMPTS TO DISCOVER GENERAL LAWS IN GEOLOGY.

Sect. L.—General Geological Phenomena.

DESIDES thus noticing such features in the rocks D of each country as were necessary to the identification of the strata, geologists have had many other phenomena of the earth's surface and materials presented to their notice; and these they have, to a certain extent, attempted to generalize, so as to obtain on this subject what we have elsewhere termed the Laws of Phenomena, which are the best materials for physical theory. Without dwelling long upon these, we may briefly note some of the most obvious. Thus it has been observed that mountain ranges often consist of a ridge of subjacent rock, on which he, on each aide, strata sloping from the ridge. Such a ridge is an Anticlinal Line, a Mineralogical Axis. The sloping strata present their Escarpments, or steep edges, to this axis. Again, in mining countries, the Veins which contain the ore are usually a system of parallel and nearly vertical partitions in the rock; and these are, in very many cases, intersected by another system of veins parallel to each other, and nearly perpendicular to the former. Rocky regions are often intersected by Faults, or fissures interrupting the strata, in which the rock on one side the fissure appears to have been at first continuous with that on the other, and shoved aside or up or down after the fracture. Again, bendes these larger fractures, rocks have Joints,—separations, or tendencies to separate in some directions rather than in others; and a slaty Cleavage, in which the parallel aubdivisions may be carried on, so as to produce laming of indefinite thinness. As an example of those

hws of phenomena of which we have spoken, we may instance the general law asserted by Prof. Sedgwick, (not, however, as free from exception,) that in one particular class of rocks the slaty Cleavage never coincides with the Direction of the strats.

The phenomena of metalliferous veins may be referred to, as another large class of facts which demand the notice of the geologist. It would be difficult to point out briefly any general laws which prevail in such cases; but in order to show the curious and complex nature of the facts, it may be sufficient to refer to the description of the metallic veins of Cornwall by Mr Carne; in which the author maintains that their various contents, and the manner in which they cut across, and stop, or shift, each other, leads naturally to the assumption of veins of no less than six or eight different ages in one kind of rock.

Again, as important characters belonging to the physical history of the earth, and therefore to geology, we may notice all the general laws which refer to its temperature;—both the laws of climate, as determined by the isothermal lines, which Humboldt has drawn, by the aid of very numerous observations made in all parts of the world; and also those still more curious facts, of the increase of temperature which takes place as we descend in the solid mass. The latter circumstance, after being for a while rejected as a fable, or explained away as an accident, is now generally acknowledged to be the true state of things in many distant parts of the globe, and probably in all.

Again, to turn to cases of another kind: some writers have endeavoured to state in a general manner have according to which the members of the geological series succeed each other; and to reduce apparent anomalies to order of a wider kind. Among those who have written with such views, we may notice alexander von Humboldt, always, and in all sciences, foremost in the race of generalization. In his attempt to extend the doctrine of geological equivalents from

¹ Transactions of the Geol. Soc. of Cornwall, vol. 11.

the rocks of Europe² to those of the Andes, he had marked by appropriate terms the general modes of geological succession. 'I have insisted,' he says' principally upon the phenomena of alternation, and local suppression, and on those presented by the passages of formations from one to another, by

the effect of an interior development.'

The phenomena of alternation to which M de Humboldt here refers are, in fact, very curious si exhibiting a mode in which the transitions from one formation to another may become gradual and insensible, instead of sudden and abrupt. Thus the coal measures in the south of England are above the mountain limestone, and the distinction of the formstions is of the most marked kind. But as we advance northward into the coal-field of Yorkshire and Durham. the subjacent limestone begins to be subdivided by thick masses of sandstone and carbonaceous strata and passes into a complex deposit, not distinguishable from the overlying coal measures; and in this manner the transition from the limestone to the coal is made by alternation. Thus, to use another expression of M. de Humboldt's, in ascending from the limestone, the coal. before we quit the subjacent stratum, preludes to its fuller exhibition in the superior beds.

Again, as to another point: geologists have gone on up to the present time endeavouring to discover general laws and facts, with regard to the position of mountain and mineral masses upon the surface of the earth. Thus M. Von Buch, in his physical description of the Canaries, has given a masterly description of the lines of volcanic action and volcanic products, all over the globe. And, more recently, M. Elie de Beaumont has offered some generalizations of a still wider kind. In this new doctrine, those mountain ranges, even in distant parts of the world, which are of the same age, according to the classifications already

Oissement des Roches dans les deux Hémisphères, 1823.
 Pref p vi.

men of, are asserted to be parallel to each other, the those ranges which are of different ages lie in ferent directions. This very wide and striking proition may be considered as being at present upon trial among the geologists of Europe.

Among the organic phenomena, also, which have the subject of geological study, general laws of a ry wide and comprehensive kind have been suggested, d in a greater or less degree confirmed by adequate amblages of facts. Thus M. Adolphe Brongniart not only, in his Fossil Flora, represented and Ifally restored a vast number of the plants of the ment world; but he has also, in the Prodromus of work, presented various important and striking two of the general character of the vegetation of mer periods, as insular or continental, tropical or inperate. And M. Agassiz, by the examination of incredible number of specimens and collections of il fish, has been led to results which, expressed in ms of his own ichthyological classification, form parkable general laws. Thus, according to him, men we go below the lias, we lose all traces of two of s four orders under which he comprehends all known ads of fish; namely, the Cycloidean and the Ctenoïwhile the other two orders, the Ganoidean and socidean, rare in our days, suddenly appear in great mbers, together with large sauroid and carnivorous Les. Cuvier, in constructing his great work on ichpology, transferred to M. Agassiz the whole subject sossil fishes, thus showing how highly he esteemed

Mr Lyell, in the sixth edition false. mbated the hypothesis of M. Soc. 1835, p. 19 m de Beaumont, stated in the

We may observe that the text. He has argued both against son of parallelism, when applied the catastrophic character of the Hues drawn on remote portions elevation of mountain chains, and a globular surface, requires to the parallelism of the contemporainterpreted in so arbitrary a neous ridges. It is evident that mer, that we can hardly ima- the former doctrine may be true, is to express a physical law though the latter be shown to be

his Principles, B. i c xil , has 6 Greenough, Address to Gool,

his talents as a naturalist. And M. Agassiz has shown himself worthy of his great predecessor in geological natural history, not only by his acuteness and activity, but by the comprehensive character of his zoological philosophy, and by the courage with which he has addressed himself to the vast labours which lie before him. In his Report on the Fossil Fish discovered is England, published in 1835, he briefly sketches some of the large questions which his researches have suggested; and then adds, Such is the meagre outline of a history of the highest interest, full of currous episodes, but most difficult to relate. To unfold the details which it contains will be the business of my life.

[2nd Ed.] [In proceeding downwards through the series of formations into which geologists have distributed the rocks of the earth, one class of organic forms after another is found to disappear. In the Tertiary Period we find all the classes of the present world: Mammals, Birds, Reptiles, Fishes, Crustaceous, Mollusks, Zoophytes. In the Secondary Period, from the Chalk down to the New Red Sandstone, Mammals are not found, with the minute exception of the marsupial amphitherium and phascolotherium in the Stonesfield slate. In the Carboniferous and Devonian period we have no large Reptiles, with, again, a minute amount of exception. In the lower part of the Silurian rocks, Fishes vanish, and we have no animal forms but Mollusks, Crustaceans and Zoophytes.

The Carboniferous, Devonian and Silurian formations, thus containing the oldest forms of life, have been termed palarozoic. The boundaries of the lifebearing series have not yet been determined; but the series has in which vertebrated animals do not appear been provisionally termed protozoic, and the lower Silurian rocks may probably be looked upon as its upper members. Below this, geologists place a hypozoic

or azoic series of rocks.

Geologists differ as to the question whether these changes in the inhabitants of the globe were made

⁷ Bril Assoc. Report, p. 72.

Agassiz has been led to the conviction that the arganized population of the globe was renewed in the nterval of each principal member of its formations. It. Lyell, on the other hand, conceives that the change in the collection of organized beings was gradual, and has proposed on this subject an hypothesis which I hall hereafter consider.]

Sect. 2 .- Transition to Geological Dynamics.

While we have been giving this account of the objects with which Descriptive Geology is occupied, it must have been felt how difficult it is, in contemplating such hets, to confine ourselves to description and classification. Conjectures and reasonings respecting the causes of the phenomena force themselves upon us at every tep, and even influence our classification and nomenclature. Our Descriptive Geology impels us to endeavour to construct a Physical Geology. This close connexion of the two branches of the subject by no means invalidates the necessity of distinguishing them:

In Botany, although the formation of a Natural System necessarily brings us to physiological relations, we still distinguish Systematic from Physiological Botany.

Supposing, however, our Descriptive Geology to be completed, as far as can be done without considering closely the causes by which the strata have been produced, we have now to enter upon the other province of the science, which treats of those causes, and of which we have already spoken, as *Physical Geology*. But before we can treat this department of speculation in a manner suitable to the conditions of science, and to the analogy of other parts of our knowledge, a certain intermediate and preparatory science must be formed, of which we shall now consider the origin and

progress.

Brit Assoc. Report, 1842, p. 83.

GEOLOGICAL DYNAMICS.

CHAPTER V.

INORGANIC GEOLOGICAL DYNAMICS.

Sect. 1.—Necessity and Object of a Science of Geological Dynamics.

THEN the structure and arrangement which mot observed in the materials of the earth instigated them to speculate concerning the past changes and revolutions by which such results had been produced they at first supposed themselves sufficiently able to judge what would be the effects of any of the obvious agents of change, as water or volcanic fire. It did not at once occur to them to suspect, that their common and extemporaneous judgment on such points was far from sufficient for sound knowledge; -they did not foresee that they must create a special science, whose object should be to estimate the general laws and effects of assumed causes, before they could pronounce whether such causes had actually produced the partcular facts which their survey of the earth had disclosed to them.

Yet the analogy of the progress of knowledge another subjects points out very clearly the necessity of such a science. When phenomenal astronomy had arrived at a high point of completeness, by the labour of ages, and especially by the discovery of Kepleri laws, astronomers were vehomently desirous of knowing the causes of these motions; and sanguine measuch as Kepler, readily conjectured that the motion were the effects of certain virtues and influences by which the heavenly bodies acted upon each other. But it did not at first occur to him and his fellow-speculators, that they had not ascertained what motions the

that, therefore, they were not prepared to judge other such causes as they spoke of, did really regulate the motions of the planets. Yet such was found be the necessary course of sound inference. Menuded a science of motion, in order to arrive at a mode of the heavenly motions: they could not adnote in the study of the Mechanics of the heavens,

they had learned the Mechanics of terrestrial lies. And thus they were, in such speculations, at thank for nearly a century, from the time of Kepler the time of Newton, while the science of Mechanics formed by Galileo and his successors. Till that it was executed, all the attempts to assign the mess of cosmical phenomena were fanciful guesses it vague assertions; after that was done, they became monstrations. The science of Dynamics enabled ilosophers to pass securely and completely from momenal Astronomy to Physical Astronomy.

In the manner, in order that we may advance from senomenal Geology to Physical Geology, we need a lance of Geological Dynamics;—that is, a science tich shall investigate and determine the laws and resequences of the known causes of changes such as one which Geology considers;—and which shall do in not in an occasional, imperfect, and unconnected tenner, but by systematic, complete, and conclusive thods,—shall, in short, be a Science, and not a pro-

acuous assemblage of desultory essays.

The necessity of such a study, as a distinct branch geology, is perhaps hardly yet formally recognized, though the researches which belong to it have, of the years, assumed a much more methodical and tentific character than they before possessed. Mr. rell's work (Principles of Geology) in particular, has amently contributed to place Geological Dynamics, its proper prominent position. Of the four books his Treatise, the second and third are upon this vision of the subject, the second book treating of meous and igneous causes of change, and the third, of larges in the organic world.

There is no difficulty in separating this annihing geological science from theoretical Geology itself, is which we apply our principles to the explanation of the actual tacts of the earth's surface. The former of perfected, would be a demonstrative science dealing with general cases; the latter is an ætiological view having reference to special facts: the one attempts to determine what always must be under given conditions; the other is satisfied with knowing what is and has been, and why it has been: the first study has a strong resemblance to Mechanics, the other to philosophical Archæology.

Since this portion of science is still so new, it is scarcely possible to give any historical account of its progress, or any complete survey of its shape and component parts. I can only attempt a few notices, which may enable us in some measure to judge to what point

this division of our subject is tending.

We may remark, in this as in former cases, that since we have here to consider the formation and progress of a science, we must treat as unimportant preludes to its history, the detached and casual observations of the effects of causes of change which we find in older writers. It is only when we come to systematic collections of information, such as may afford the means of drawing general conclusions, or to reprove deductions from known laws of nature,—that we can recognize the separate existence of geological dynamics, as a path of scientific research.

The following may perhaps suffice, for the present, as a sketch of the subjects of which this science treats:—the aqueous causes of change, or those in which water adds to, takes from, or transfers, the materials of the land:—the igneous causes; volcanoes, and, closely connected with them, earthquakes, and the forces by which they are produced;—the calculations which determine, on physical principles, the effects of assumed mechanical causes acting upon large portions of the crust of the earth;—the effect of the forces, whatever they be, which produce the crystalline texture of rocks, their fissile structure, and the separate

for of materials, of which we see the results in metalferous veins. Again, the estimation of the results of
hanges of temperature in the earth, whether operating
by pressure, expansion, or in any other way;—the
fects of assumed changes in the superficial condition,
attent, and elevation, of terrestrial continents upon
the climates of the earth;—the effect of assumed cosmical changes upon the temperature of this planet;—
and researches of the same nature as these.

These researches are concerned with the causes of hange in the inorganic world; but the subject requires less that we should investigate the causes which may modify the forms and condition of organic things; ad in the large sense in which we have to use the parase, we may include researches on such subjects lao as parts of Geological Dynamics; although, in truth, this department of physiology has been cultirated, as it well deserves to be, independently of its caring upon geological theories. The great problem which offers itself here, in reference to Geology, 18, to *xamine the value of any hypotheses by which it may be attempted to explain the succession of different saces of animals and plants in different strata; and though it may be difficult, in this inquiry, to arrive at my positive result, we may at least be able to show the improbability of some conjectures which have been propounded.

I shall now give a very brief account of some of the attempts made in these various departments of this province of our knowledge; and in the present chapter, of Inorganic Changes.

Sect. 2 .- Aqueous Causes of Change.

THE controversies to which the various theories of geologists gave rise, proceeding in various ways upon the effects of the existing causes of change, led men to observe, with some attention and perseverance, the actual operation of such causes. In this way, the known effect of the Rhine, in filling up the luke of Geneva at its upper extremity, was referred to by

De Luc, Kirwan, and others, in their dispute with the Huttonians; and attempts were even made to calculate how distant the period was, when this alluvial depost first began. Other modern observers have attended to similar facts in the natural history of rivers and seas. But the subject may be considered as having first assumed its proper form, when taken up by Mr Von Hoff, of whose History of the Natural Change of the Earth's Surface which are proved by Tradition, the first part, treating of aqueous changes, appeared in 1822. This work was occasioned by a Prize Question of the Royal Society of Gottingen, promulgated a 1818; in which these changes were proposed as the subject of inquiry, with a special reference to geologic Although Von Hoff does not attempt to establish any general inductions upon the facts which his book cortains, the collection of such a body of facts gave almost a new aspect to the subject, by showing that changes in the relative extent of land and water were going on at every time, and almost at every place; and that mutability and fluctuation in the form of the sold parts of the earth, which had been supposed by most persons to be a rare exception to the common course of events, was, in fact, the universal rule. But it was Mr. Lyell's Principles of Geology, being an attempt to explain the former Changes of the Earth's Surface by the Causes now in action, (of which the first volume was published in 1830,) which disclosed the full effect of such researches on geology; and which attempted to present such assemblages of special facts, as examples of general laws. Thus this work may, as we have said, be looked upon as the beginning of Geological Dynamics, at least among us. Such generalizations and applications as it contains give the most hvely interest to a thousand observations respecting river and floods, mountains and morasses, which otherwise appear without aim or meaning; and thus this department of science cannot fail to be constantly augmented by contributions from every side. At the same time it is clear, that these contributions, voluminous as they must become, must, from time to time, be resolved

into laws of greater and greater generality; and that thus alone the progress of this, as of all other sciences, can be furthered.

I need not attempt any detailed enumeration of the modes of squeous action which are here to be considered. Some are destructive, as when the rivers erode the channels in which they flow; or when the waves, by their perpetual assault, shatter the shores, and carry the ruins of them into the abyss of the ocean. Some operations of the water, on the other hand, add to the land; as when deltas are formed at the mouths of rivers, or when calcareous springs form deposits of travertin. Even when bound in icy fetters, water is by no means deprived of its active power; the glacier carries into the valley masses of its native mountain, and often, becoming ice-bergs, float with a lading of such materials far into the seas of the temperate zone. It is indisputable that vast beds of worndown fragments of the existing land are now forming into strata at the bottom of the ocean; and that many other effects are constantly produced by existing aqueous causes, which resemble some, at least, of the

facts which geology has to explain.

[2nd Ed.] [The effects of glaciers above mentioned are obvious, but the mechanism of these bodies, -the mechanical cause of their motions,—was an unsolved problem till within a very few years. That they slide as rigid masses;—that they advance by the expansion of their mass;—that they advance as a collection of rigid fragments, were doctrines which were held by eminent physicists, though a very slight attention to the subject shows these opinions to be untenable. In Professor James Forbes's theory on the subject (published in his Travels through the Alps, 1843.) we find a solution of the problem, so simple, and yet so exact, as to produce the most entire conviction. In this theory, the ice of a glacier is, on a great scale, supposed to be a plastic or viscous mass, though small portions of it are sensibly rigid. It advances down the slope of the valley in which it lies as a plastic mass would do, accommodating itself to the varying shape and size of its bed, and showing by its crevasses its mixed character between fluid and rigid. It shows this character still more curiously by a ribboned structure on a sun scale, which is common in the solid ice of the glacer The planes of these ribbons are, for the most part it right angles to the crevasses, near the sides of the glacier, while, near its central line, they dip toward the upper part of the glacier. This structure appear to arise from the difference of velocities of contiguous moving filaments of the icy mass, as the crevases themselves arise from the tension of larger portions Mr. Forbes has, in successive publications, removed the objections which have been urged against the theory. In the last of them, a Memoir in the Phil. Trans., 1846, (Illustrations of the Viscous Theory of Glacier Motion,) he very naturally expresses astonishment at the opposition which has been made to the theory on the ground of the rigidity of small pieces of ice. He has himself shown that the ice of glaciers has a plastic flexibility, by marking forty-five points in a transverse straight line upon the Mer de Glace, and observing them for several days. The straight line in that time not only became oblique to the side, but also became visibly curved.

Both Mr. Forbes and other philosophers have made it in the highest degree probable that glaciers have existed in many places in which they now exist no longer, and have exercised great powers in transporting large blocks of rock, furrowing and polishing the rocks along which they slide, and leaving lines and masses of detritus or moraine which they had carried along with them or pushed before them. It cannot be doubted that extinct glaciers have produced some of the effects which the geologist has to endeavour to explain. But this part of the machinery of nature has been worked by some theorists into an exaggerated form, in which it cannot, as I conceive, have any place in an account of Geological Dynamics which aims at

being permanent.

The great problem of the diffusion of drift and erratic blocks from their parent rocks to great du-

tances, has driven geologists to the consideration of other hypothetical machinery by which the effects may be accounted for: especially the great northern drift and boulders,—the rocks from the Scandinavian chain which cover the north of Europe on a vast area, having a length of 2000 and breadth of from 400 to 800 miles. The diffusion of these blocks has been accounted for by supposing them to be imbedded in icebergs, detached from the shore, and floated into oceanic spaces, where they have grounded and been deposited by the melting of the ice. And this mode of action may to some extent be safely admitted into geological speculation. For it is a matter of fact, that our navigators in arctic and antarctic regions have repeatedly seen icebergs and icefloes sailing along laden with such materials.

The above explanation of the phenomena of drift supposes the land on which the travelled materials are found to have been the bottom of a sea where they were deposited. But it does not, even granting the conditions, account for some of the facts observed;that the drift and the boulders are deposited in 'trainées' or streaks, which, in direction, diverge from the parent rock :—and that the boulders are of smaller and smaller size, as they are found more remote from that center These phenomena rather suggest the notion of currents of water as the cause of the distribution of the materials into their present situations. And though the supposition that the whole area occupied by drift and boulders was a sea-bottom when they were scattered over it much reduces the amount of violence which it is necessary to assume in order to distribute the loose masses, yet still the work appears to be beyond the possible effect of ordinary marine currents, or any movements which would be occasioned by a slow and gradual rising of the center of distribution.

It has been suggested that a sudden rise of the center of distribution would cause a motion in the surrounding ocean sufficient to produce such an effect: and in confirmation of this, reference have been made to Mr. Scott Russell's investigations with respect to waves, already referred to. (Book viti.) The wave a this case would be the wave of trunslation, in which the motion of the water is as great at the bottom is at the top; and it has hence been asserted that by paroxysmal elevations of 100 or 200 feet, a current of 25 or 30 miles an hour might be accounted for. LA I think it has not been sufficiently noted that at care point this 'current' is transient: it lasts only while the wave is passing over the point, and therefore it would only either carry a single mass the whole way with its own velocity, or move through a short detance a series of masses over which it successively passed. It does not appear, therefore, that we have here a complete account of the transport of a collection of materials, in which each part is transferred through great distances: -except, indeed, we were to suppose numerous succession of paroxysmal elevations. Such . battery might, by successive shocks, transmitting ther force through the water, diffuse the fragments of the central mass over any area, however wide.

The fact that the erratic blocks are found to rest on the lower drift, is well explained by supposing the latter to have been spread on the sea bottom while rock-bearing ice masses floated on the surface till they

deposited their lading.

Sir R. Murchison has pointed out another operation of ice in producing mounds of rocky masses; namely, the effects of rivers and lakes, in climates where, as a Russia, the waters carry rocky fragments entangled at the winter ice, and leave them in heaps at the highest level which the waters attain.

The extent to which the effects of glaciers, now vanished, are apparent in many places, especially in Switzerland and in England, and other phenomena of the like tendency, have led some of the most eminent geologists to the conviction that, anterior to the period of our present temperature, there was a Glacial Period, at which the temperature of Europe was lower than it now is.]

Although the study of the common operations of

water may give the geologist such an acquaintance with the laws of his subject as may much aid his judgment respecting the extent to which such effects may proceed, a long course of observation and thought must be requisite before such operations can be analysed into their fundamental principles, and become the subjects of calculation, or of rigorous reasoning in any manner which is as precise and certain as calculation. Various portions of Hydraulies have an important bearing upon these subjects, including some researches which have been pursued with no small labour by engineers and mathematicians; as the effects of currents and waves, the laws of tides and of rivers, and many similar problems. In truth, however, such subjects have not hitherto been treated by mathematicians with much success; and probably several generations must elapse before this portion of geological dynamics can become an exact science.

Sect. 3 .- Igneous Causes of Change .- Motions of the Earth's Surface.

THE effects of volcanoes have long been noted as important and striking features in the physical history of our globe; and the probability of their connexion with many geological phenomena, had not escaped notice at an early period. But it was not till more recent times, that the full import of these phenomena was apprehended. The person who first looked at such operations with that commanding general view which showed their extensive connexion with physical geology, was Alexander von Humboldt, who explored the volcanic phenomena of the New World, from 1799 He remarked the linear distribution of volcame domes, considering them as vents placed along the edge of vast fissures communicating with reservoirs of igneous matter, and extending across whole continents. He observed, also, the frequent sympathy of volcanic and terremotive action in remote districts of

Hamboldt, Relation Historique; and his other works

the earth's surface, thus showing how deeply seated must be the cause of these convulsions. These views strongly excited and influenced the speculations of geologists; and since then, phenomena of this kind have been collected into a general view as parts of a Von Hoff, in the second natural-historical science. volume of the work already mentioned, was one of the first who did this; 'At least,' he himself says,2 (1824) it was not known to him that any one before Lu had endeavoured to combine so large a mass of fau with the general ideas of the natural philosopher, so as to form a whole.' Other attempts were, however, soon made. In 1825, M. von Ungern Sternberg published his book On the Nature and Origin of Volcanous! in which, he says, his object is, to give an empired representation of these phenomens. In the same year, Mr. Poulett Scrope published a work in which be described the known facts of volcanic action, not however, confining himself to description; his purpose being, as his title states, to consider 'the probable causes of their phenomena, the laws which determine their march, the disposition of their products, and their connexion with the present state and past history of the globe; leading to the establishment of a new theory of the earth.' And in 1826, Dr. Daubeny, of Oxford, produced A Description of Active and Extinct Volcanoes, including in the latter phrase, the volcanic rocks of central France, of the Rhine, of northern and central Italy, and many other countries. near connexion between the volcanic effects now going on, and those by which the basaltic rocks of Auvergue and many other places had been produced, was, by this time, no longer doubted by any, and therefore the line which here separates the study of existing causes from that of past effects may seem to melt away. But yet it is manifest that the assumption of an identity of scale and mechanism between volcanoes now active, and the igneous catastrophes of which the

² Vol it Prop. 5.

¹ Werden und Sryn des Vulkanischen Gebirges Cartaruhe, 1845.

products have survived great revolutions on the earth's surface, is hypothetical; and all which depends on this

assumption belongs to theoretical geology.

Contining ourselves, then, to volcanic effects, which have been produced, certainly or probably, since the earth's surface assumed its present form, we have still an ample exhibition of powerful causes of change, in the streams of lava and other materials emitted in eruptions, and still more in the earthquakes which, as men easily satisfied themselves, are produced by the

same causes as the eruptions of volcanic fire.

Mr. Lyell's work was important in this as in other portions of this subject. He extended the conceptions previously entertained of the effects which such causes may produce, not only by showing how great these operations are historically known to have been, and how constantly they are going on, if we take into our survey the whole surface of the earth; but still more, by urging the consequences which would follow in a long course of time from the constant repetition of operations in themselves of no extraordinary amount. A lava-stream many miles long and wide, and several yards deep, a subsidence or elevation of a portion of the earth's surface of a few feet, are by no means extraordinary facts. Let these operations, said Mr. Lyell, be repeated thousands of times; and we have results of the same order with the changes which geology discloses.

The most mitigated earthquakes have, however, a character of violence. But it has been thought by many philosophers that there is evidence of a change of level of the land in cases where none of these violent operations are going on. The most celebrated of these cases is Sweden; the whole of the land from Gottenburg to the north of the Gulf of Bothnia has been supposed in the act of rising, slowly and insensibly, from the surrounding waters. The opinion of such a change of level has long been the belief of the inhabitants; and was maintained by Celsius in the beginning of the eighteenth century. It has since been conceived to be confirmed by various observations of marks cut on the

face of the rock; beds of shells, such as now live in the neighbouring seas, raised to a considerable height; and other indications. Some of these proofs appear doubtful; but Mr. Lyell, after examining the facts upon the spot in 1834, says, 'In regard to the proposition that the land, in certain parts of Sweden, is gradually rising. I have no hesitation in assenting to it, after my visit to the districts above alluded to.' If this conclusion be generally accepted by geologists, we have here a daily example of the operation of some powerful agent which belongs to geological dynamics; and which to the purposes of the geological theorist, does the work of the earthquake upon a very large scale, without

assuming its terrors.

[2nd Ed.] [Examples of changes of level of large districts occurring at periods when the country has been agitated by earthquakes are well ascertained, w the rising of the coast of Chili in 1822, and the subsidence of the district of Cutch, in the delta of the Indus, in 1819. (Lyell, B. H. c. xv.) But the cases of more slow and tranquil movement seem also to be established. The gradual secular rise of the shore of the Baltic, mentioned in the text, has been confirmed by subsequent investigation. It appears that the rate of elevation increases from Stockholm, where it is only a few inches in a century, to the North Cape, where it is several feet. It appears also that several other regions are in a like state of secular change. The coast of Greenland is sinking. (Lyell, B. II. c. xviii.) And the existence of 'raised beaches' along various coasts is now generally accepted among geologists. Such beaches, anciently forming the margin of the sea, but now far above it, exist in many places; for instance, along a great part of the Scotch coast, and among the raised beaches of that country we ought probably, with Mr. Darwin, to include the 'parallel roads' of Glenroy, the subject, in former days, of so much controversy among geologists and antiquaries.

Connected with the secular rise and fall of large

⁴ Phil. Trans 1835, p 3a.

portions of the earth's surface, another agency which plays an important part in Geological Dynamics has been the subject of some bold yet singularly persuasive speculations by Mr. Darwin. I speak of the formation of Coral, and Coral Reefs. He says that the coralbuilding animal works only at small and definite distances below the surface How then are we to account for the vast number of coral islands, rings, and reefs, which are scattered over the Pacific and Indian Oceans? Can we suppose that there are so many mountains, craters, and ridges, all exactly within a few feet of the same height through this vast portion of the globe's surface? This is incredible. How then are we to explain the facts? Mr. Darwin replies, that if we suppose the land to subside slowly beneath the sea, and at the same time suppose the coralline zoophytes to go on building, so that their structure constantly rises nearly to the surface of the water, we shall have the facts explained. A submerged island will produce a ring; a long coast, a barrier reef; and so on. Mr. Darwin also notes other phenomena, as elevated beds of coral, which, occurring in other places, indicate a recent rising of the land; and on such grounds as these he divides the surface of those parts of the ocean into regions of elevation and of depression.

The labours of coralline zoophytes, as thus observed. form masses of coral, such as are found fossilized in the strata of the earth. But our knowledge of the laws of life which have probably affected the distribution of marine remains in strata, has received other very striking accessions by the labours of Prof. Edward Forbes in observing the marine animals of the Ægean Sea. He found that, even in their living state, the mollusks and zoophytes are already distributed into strata. Dividing the depth into eight regions, from 2 to 230 fathoms, he found that each region had its peculiar inhabitants, which disappeared speedily either in ascending or in descending. The zero of animal life appeared to occur at about 300 fathoms. This curious result bears in various ways upon geology. Mr. Forbes himself has given an example of the mode in which it may be applied, by determining the depth at which the submarine eruption took place which produced the volcanic isle of Neokaimeni in 1707. By an examination of the fossils embedded in the pumice, he showed

that it came from the fourth region.5

To the modes in which organized beings operate a producing the materials of the earth, we must aid those pointed out by the extraordinary microscopic decoveries of Professor Ehrenberg. It appears that whole beds of earthy matter consist of the cases of certain infusoria, the remains of these creatures being accumulated in numbers which it confounds our thoughts to

contemplate.

Speculations concerning the causes of volcanoes and earthquakes, and of the rising and sinking of land, are a highly-important portion of this science, at least as far as the calculation of the possible results of definite causes is concerned. But the various hypotheses which have been propounded on this subject can hardly be considered as sufficiently matured for such calculation. A mass of matter in a state of igneous fusion, extending to the center of the earth, even if we make such an hypothesis, requires some additional cause to produce eruption. The supposition that this fire may be produced by intense chemical action between combining elements, requires further, not only some agency to bring together such elements, but some reason why they should be originally separate. And if any other causes have been suggested, as electricity or magnetism, this has been done so vaguely as to elude all possibility of rigorous deduction from the hypothesis. The doctrine of a Central Heat, however, has occupied so considerable a place in theoretical geology, that it ought undoubtedly to form an article in geological dynamics.

Sect. 4 .- The Doctrine of Central Heat.

THE early geological theorists who, like Leibnitz and Buffon, assumed that the earth was originally a mass in a state of igneous fusion, naturally went on to deduce

British Assoc. Reports, 1843, p. 177

from this hypothesis, that the crust consolidated and cooled before the interior, and that there might still remain a central heat, capable of producing many important effects. But it is in more recent times that we have measures of such effects, and calculations which we can compare with measures. It was found, as we have said, that in descending below the surface of the earth, the temperature of its materials increased. Now it followed from Fourier's mathematical investications of the distribution of heat in the earth, that if there be no primitive heat, (chaleur d'origine,) the temperature, when we descend below the crust, will be constant in each vertical line. Hence an observed increase of temperature in descending, appeared to point out a central heat resulting from some cause now no longer in action.

The doctrine of a central heat has usually been combined with the supposition of a central igneous fluidity; for the heat in the neighbourhood of the center must be very intense, according to any law of its increase in descending which is consistent with known principles. But to this central fluidity it has been objected that such a fluid must be in constant circulation by the cooling of its exterior. Mr. Daniell found this to be the case in all fused metals. It has also been objected that there must be, in such a central fluid, tides produced by the moon and sun; but this inference would require several additional suppositions and calculations

to give it a precise form.

Again, the supposition of a central heat of the earth, considered as the effect of a more ancient state of its mass, appeared to indicate that its cooling must still be going on. But if this were so, the earth might contract, as most bodies do when they cool; and this contraction might lead to mechanical results, as the shortening of the day. Laplace satisfied himself, by reference to ancient astronomical records, that no such alteration in the length of the day had taken place, even to the amount of one two-hundredth of a second; and thus, there was here no confirmation of the hypothesis of a primitive heat of the earth.

Though we find no evidence of the secular contrition of the earth in the observations with which astrnomy deals, there are some geological facts which a first appear to point to the reality of a refrigerate: within geological periods; as the existence of toremains of plants and shells of tropical climates, in the strata of countries which are now near to or with the frigid zones. These facts, however, have given by to theories of the changes of climate, which we must

consider separately.

But we may notice, as connected with the doctru of central heat, the manner in which this hypothesis has been applied to explain volcanic and geological phenomena. It does not enter into my plan, to consider explanations in which this central heat is supposed to give rise to an expansive force,6 without any distinct reference to known physical laws. But we may notice, as more likely to become useful materials of the science now before us, such speculations as these of Mr Babbage; in which he combines the doctrine of central heat with other physical laws,7 as, that sold rocks expand by being heated, but that clay contracts; that different rocks and strata conduct heat differentis; that the earth radiates heat differently, or at different parts of its surface, according as it is covered with forests, with mountains, with deserts, or with water. These principles, applied to large masses, such as there which constitute the crust of the earth, might give rise to changes as great as any which geology discloses. For example: when the bed of a sea is covered by a thick deposit of new matter worn from the shores, the strata below the bed, being protected by a had conductor of heat, will be heated, and, being heated, may be expanded; or, as Sir J. Herschel has observed, may produce explosion by the conversion of their moisture into steam. Such speculations, when founded on real

ata and sound calculations, may hereafter be of mate-

tial use in geology.

The doctrine of central heat and fluidity has been rejected by some eminent philosophers. Mr. Lyell's reasons for this rejection belong rather to Theoretical Beology, but I may here notice M. Poisson's opinion. He does not assent to the conclusion of Fourier, that ince the temperature increases in descending, there must be some primitive central heat. On the contrary, he considers that such an increase may arise from this, -that the earth, at some former period, passed by the motion of the solar system in the universe,) through a portion of space which was warmer than the space in which it now revolves (by reason, it may be, of the heat of other stars to which it was then mearer). He supposes that, since such a period, the parface has cooled down by the influence of the surcounding circumstances; while the interior, for a certain unknown depth, retains the trace of the former elevation of temperature. But this assumption is not likely to expel the belief in the terrestrial origin of the subterraneous heat. For the supposition of such m mequality in the temperature of the different regions in which the solar system is placed at different times, is altogether arbitrary; and, if pushed to the amount to which it must be carried, in order to account for the phenomenon, is highly improbable.8 The doctrine of central heat, on the other hand, (which need not be conceived as implying the universal Amdity of the mass.) is not only naturally suggested by the subterraneous increase of temperatures, but

the earth has, at some former past operation of forces, fitted to period, derived from some other obliterate all order and symmetry, star or stars more heat than she is quite inconsistent with the now derives from the sun But simple, regular, and symmetrical this would imply, as highly pro- relation which the whole solar bable, that at some period some system, as far as Uranus, bears to other star or stars must have pro- the present central body. daced also a mechanical effect upon

explains the spheroidal figure of the earth; and the in with almost any theory which can be devised, it volcanoes, earthquakes, and great geological changes

Sect. 5.—Problems respecting Elevations and Crystalline Forces.

OTHER problems respecting the forces by which grat masses of the earth's crust have been displaced, lan also been solved by various mathematicians. It is been maintained by Von Buch that there occur, a various places, craters of elevation. that is, mountain masses resembling the craters of volcanoes, but reals produced by an expansive force from below, burstug an aperture through horizontal strata, and elevating them in a conical form Against this doctrine w exemplified in the most noted instances, strong arguments have been adduced by other geologists. Yes the protrusion of fused rock by subterraneous forces upon a large scale is not denied: and how far the examples of such operations may, in any cases, be termed craters of elevation, must be considered as a question not yet decided. On the supposition of the truth of Von Buch's doctrine, M. de Beaumont has calculated the relations of position, the fissures de, which would arise. And Mr. Hopkins, 9 of Cambridge has investigated in a much more general manner upon mechanical principles, the laws of the elevations. fissures, faults, veins, and other phenomena which would result from an elevatory force, acting simu. taneously at every point beneath extensive portions of the crust of the earth. An application of mathema tical reasoning to the illustration of the phenomena of veins had before been made in Germany by Schmidt and Zimmerman, 10 The conclusions which Mr. Hopkins has obtained, respecting the two sets of fissures, at right angles to each other, which would in general be produced by such forces as he supposes, may suggest

⁹ Trans. Camb. Phil. Soc. vol. vi 1836.

INORGANIC GEOLOGICAL DYNAMICS.

cal phenomena of fissured districts.

and Ed. The theory of craters of elevation pro-Bly errs rather by making the elevation of a point a particular class of volcanic agency, than by ing volcame agency too great a power of elevation. A mature consideration of the subject will make us itate to ascribe much value to the labours of those iters who have applied mathematical reasoning to logical questions. Such reasoning, when it is ried to the extent which requires symbolical proes, has always been, I conceive, a source, not of wledge, but of errour and confusion; for in such lications the real questions are slurred over in the othetical assumptions of the mathematician, while calculation misleads its followers by a false aspect emonstration. All symbolical reasonings concernthe fissures of a semi-rigid mass produced by ratory or other forces, appear to me to have turned valueless. At the same time it cannot be too engly borne in mind, that mathematical and memical habits of thought are requisite to all clear nking on such subjects.

Other forces, still more obscure in their nature and have played a very important part in the formaof the earth's crust. I speak of the forces by ich the crystalline, slaty, and jointed structure of neral masses has been produced. These forces are hably identical, on the one hand, with the cohesive ses from which rocks derive their solidity and their pical properties; while, on the other hand, they are ely connected with the forces of chemical attraction. attempts, of any lucid and hopeful kind, have yet made to bring such forces under definite mechael conceptions: and perhaps mineralogy, to which ence, as the point of junction of chemistry and retallography, such attempts would belong, is hardly ripe for such speculations. But when we look at universal prevalence of crystalline forms and avages, at the extent of the phenomena of slaty avage, and at the segregation of special minerals

into veius and nodules, which has taken place in some unknown manner, we cannot doubt that the forces of which we now speak have acted very widely and enterprise getically. Any elucidation of their nature would be

an important step in Geological Dynamics.

[2nd Ed] [A point of Geological Dynamics of great importance is, the change which rocks undergo m structure after they are deposited, either by the actuaof subterraneous heat, or by the influence of crystalline or other corpuscular forces. By such agencies sedimentary rocks may be converted into crystall ac, the traces of organic fossils may be obliterated, a slaty cleavage may be produced, and other like effects. The possibility of such changes was urged by Dr. Hutton in his Theory; and Sir James Hall's very instructive and striking experiments were made for the purpose of illustrating this theory. In these experiments, powdered chalk was, by the application of heat under pressure, converted into crystalline calcapar. wards Dr. McCulloch's labours had an important influence in satisfying geologists of the reality of corresponding changes in nature. Dr. McCulloch, by has very lively and copious descriptions of volcanic regions. by his representations of them, by his classification of igneous rocks, and his comprehensive views of the phenomena which they exhibit, probably was the means of converting many geologists from the Wernerian opinions.

Rocks which have undergone changes since they were deposited are termed by Mr. Lyell metamorphic. The great extent of metamorphic rock changed by heat is now uncontested. The internal changes which are produced by the crystalline forces of mountain masses have been the subjects of important and comprehensive speculations by Professor Sedgwick.]

Sect. 6 .- Theories of Changes of Climate.

As we have already stated, Geology offers to us strong evidence that the climate of the ancient periods of the earth's history was hotter than that which now exists

INORGANIC GEOLOGICAL DYNAMICS.

be same countries. This, and other circumstances, led geologists to the investigation of the effects by hypothetical causes of such changes of condition

pect of heat.

he love of the contemplation of geometrical symry, as well as other reasons, suggested the hypois that the earth's axis had originally no obliquity, was perpendicular to the equator. Such a contation of the world had been thought of before the of Milton, 11 as what might be supposed to have ted when man was expelled from Paradise; and net, in his Sucred Theory of the Earth, (1690,) sted this notion of the paradisiacal condition of globe:

The spring
Perpetual smiled on earth with verdant flowers,
Equal in days and nights.

modern times, too, some persons have been could to adopt this hypothesis, because they have eived that the present polar distribution of light consistent with the production of the fossil plants the are found in those regions, 12 even if we could, one other way, account for the change of tempere. But this alteration in the axis of revolution denot take place without a subversion of the equitum of the surface, such as does not appear to have a modern to the change has of late been generally ared impossible by physical astronomers.

he effects of other astronomical changes have been plated by Sir John Herschel. He has examined, instance, the thermotical consequences of the inution of the eccentricity of the earth's orbit, the has been going on for ages beyond the records instory. He finds 13 that, on this account, the near the effect of solar radiation would increase as we

¹¹ Some say he hade his angels turn askance

¹² Lyell, i. 155. Lindley, Fossil Flora.

¹³ Geol. Trans. vol. ili. p 295.

go back to remoter periods of the past; but (probably at least) not in a degree sufficient to account for the apparent past changes of climate. He finds, however, that though the effect of this change on the mean temperature of the year may be small, the effect of the extreme temperature of the seasons will be much more considerable; 'so as to produce alternately, in the same latitude of either hemisphere, a perpetual apring, or the extreme vicissitudes of a burness

summer and a rigorous winter.'14

Mr. Lyell has traced the consequences of another hypothesis on this subject, which appears at first such to promise no very striking results, but which yet u found, upon examination, to involve adequate causes of very great changes: I refer to the supposed various distribution of land and water at different periods of the earth's history. If the land were all gathered into the neighbourhood of the poles, it would become the seat of constant ice and snow, and would thus very greatly reduce the temperature of the whole surface of the globe. If, on the other hand, the polar regions were principally water, while the tropics were occupied with a belt of land, there would be no part of the earth's surface on which the frost could fasten a firm hold, while the torrid zone would act like a furnace to heat the whole. And, supposing a cycle of terrestrial changes in which these conditions should succeed each other, the winter and summer of this 'great year,' might differ much more than the elevated temperature which we are led to ascribe to former periods of the globe, can be judged to have differed from the present state of things.

The ingenuity and plausibility of this theory cannot be doubted: and perhaps its results may hereafter be found not quite out of the reach of calculation. Some progress has already been made in calculating the movement of heat into, through, and out of the earth; but when we add to this the effects of the currents of the ocean and the atmosphere, the problem, thus involving

¹⁴ Geol, Trans. vol. iii. p. 298.

INORGANIC GEOLOGICAL DYNAMICS.

473

so many thermotical and atmological laws, operating under complex conditions, is undoubtedly one of extreme difficulty. Still, it is something, in this as in all cases, to have the problem even stated, and none of the elements of the solution appears to be of such a nature, that we need allow ourselves to yield to despair, respecting the possibility of dealing with it in a useful manner, as our knowledge becomes more complete and definite.

CHAPTER VI.

PROGRESS OF THE GEOLOGICAL DYNAMICS OF ORGANIZED BEINGS.

Sect. 1 .- Objects of this Science.

PERHAPS in extending the term Geological Dynamics to the causes of changes in organized beings, I shall be thought to be employing a forced and inconvenient phraseology. But it will be found that, morder to treat geology in a truly scientific manner, we must bring together all the classes of speculations concerning known causes of change; and the Organic Dynamics of Geology, or of Geography, if the reader prefers the word, appears not an inappropriate phrase for one part of this body of researches.

As has already been said, the species of plants and animals which are found imbedded in the strata of the earth, are not only different from those which now hve in the same regions, but, for the most part, different from any now existing on the face of the earth. The remains which we discover imply a past state of things different from that which now prevails, they imply also that the whole organic creation has been renewed, and that this renewal has taken place several times. Such extraordinary general facts have naturally put in

activity very bold speculations.

But, as has already been said, we cannot speculate upon such facts in the past history of the globe, without taking a large survey of its present condition. Does the present animal and vegetable population differ from the past, in the same way in which the products of one region of the existing earth differ from those of another? Can the creation and diffusion of the fossil species be explained in the same manner as the creation and diffusion of the creatures among which we have! And these questions lead us onwards another step, to

k,—What are the laws by which the plants and dimals of different parts of the earth differ? What in the manner in which they were originally diffused? Thus we have to include, as portions of our subject, to Geography of Plants, and of Animals, and the istory of their change and diffusion; intending by the ter subject, of course, palatiological History,—the tamination of the causes of what has occurred, and to inference of past events, from what we know of theses.

It is unnecessary for me to give at any length a stement of the problems which are included in these maches of science, or of the progress which has been ade in them; since Mr. Lyell, in his Principles of sology, has treated these subjects in a very able manner, ad in the same point of view in which I am thus led consider them. I will only briefly refer to some mats, availing myself of his labours and his ideas.

Sect. 2 .- Geography of Plants and Animals.

THE regard both to plants and animals, it appears, tat besides such differences in the products of different gions as we may naturally suppose to be occasioned climate and other external causes; an examination the whole organic population of the globe leads us consider the earth as divided into provinces, each tovince being occupied by its own group of species, d these groups not being mixed or interfused among ch other to any great extent. And thus, as the earth occupied by various nations of men, each appearing, first sight, to be of a different stock, so each other be of living things is scattered over the ground in a milar manner, and distributed into its separate nations distant countries. The places where species are thus culiarly found, are, in the case of plants, called their ations. Yet each species in its own region loves and tects some peculiar conditions of shade or exposure, d or moisture: its place defined by the general deription of such conditions, is called its habitation.

Lyell, Principles, B. iii. c. v.

Not only each species thus placed in its own province, has its position further fixed by its own habits, but more general groups and assemblages are found to be determined in their situation by more general conditions. Thus it is the character of the flora of a collection of islands, scattered through a wide ocean in a tropical and humid climate, to contain an immense preponderance of tree-ferns. In the same way, the situation and depth at which certain genera of shells are found, have been tabulated? by Mr. Brodena. Such general inferences, if they can be securely made, are of extreme interest in their bearing on geological speculations.

The means by which plants and animals are now diffused from one place to another, have been well described by Mr. Lyell.³ And he has considered also, with due attention, the manner in which they become imbedded in mineral deposits of various kinds.⁴ He has thus followed the history of organized bodies, from the germ to the tomb, and thence to the cabinet of the

geologist.

But, besides the fortunes of individual plants and animals, there is another class of questions, of great interest, but of great difficulty;—the fortunes of each species. In what manner do species which were not begin to be? as geology teaches us that they many times have done; and, as even our own reasonings convince us they must have done, at least in the case of

the species among which we live,

We here obviously place before us, as a subject of research, the Creation of Living Things; a subject shrouded in mystery, and not to be approached without reverence. But though we may conceive, that, on this subject, we are not to seek our belief from science alone, we shall find, it is asserted, within the limits of allowable and unavoidable speculation, many currous and important problems which may well employ our physiological skill. For example, we may ask:—how

² Greenough, Add. 1815, p. 20.

² Lyell, B. ill. c. v. vi. vil. 4 B. ili. c. xill. xiv. xv. xvi.

reated distinct?—whether the population of the earth one geological epoch could pass to the form which it as at a succeeding period, by the agency of natural anses alone?—and if not, what other account we can we of the succession which we find to have taken have?

The most remarkable point in the attempts to newer these and the like questions, is the controversy tween the advocates and the opponents of the doctine of the transmutation of species. This question is, wen from its mere physiological import, one of great atterest; and the interest is much enhanced by our cological researches, which again bring the question afore us in a striking form, and on a gigantic scale. We shall, therefore, briefly state the point at issue.

Sect. 3 .- Question of the Transmutation of Species.

Vz see that animals and plants may, by the influence f breeding, and of external agents operating upon heir constitution, be greatly modified, so as to give to varieties and races different from what before risted. How different, for instance, is one kind and greed of dog from another! The question, then, is, thether organized beings can, by the mere working of stural causes, pass from the type of one species to hat of another? whether the wolf may, by domesticaion, become the dog? whether the ourang-outang asy, by the power of external circumstances, be rought within the circle of the human species? And he dilemma in which we are placed is this;—that if pecies are not thus interchangeable, we must suppose he fluctuations of which each species is capable, and which are apparently indefinite, to be bounded by igorous limits; whereas, if we allow such a transnutation of species, we abandon that belief in the daptation of the structure of every creature to its lestined mode of being, which not only most persons would give up with repugnance, but which, as we tave seen, has constantly and irresistibly impressed itself on the minds of the best naturalists, as the true view of the order of the world.

But the study of Geology opens to us the spectarie of many groups of species which have, in the course (the earth's history, succeeded each other at vast murvals of time, one set of animals and plants disappearing, as it would seem, from the face of our planet, and others, which did not before exist, becoming the only occupants of the globe. And the dilemma then presents itself to us anew:-either we must accept the doctrine of the transmutation of species, and must suppose that the organized species of one geological epoch were transmuted into those of another by some long-continued agency of natural causes; or else, we must believe in many successive acts of creation and extinction of species, out of the common course of nature; acts which, therefore, we may properly call miraculous.

This latter dilemms, however, is a question concerning the facts which have happened in the history of the world; the deliberation respecting it belongs to physical geology itself, and not to that subsidiary science which we are now describing, and which is concerned only with such causes as we know to be in constant and orderly action.

The former question, of the limited or unlimited extent of the modifications of animals and plants, has received full and careful consideration from eminent physiologists: and in their opinions we find, I think, an indisputable preponderance to that decision which rejects the transmutation of species, and which accepts the former side of the dilemma; namely, that the changes of which each species is susceptible, though difficult to define in words, are limited in fact. It is extremely interesting and satisfactory thus to receive an answer in which we can confide, to inquiries seemingly so wide and bold as those which this subject involves. I refer to Mr. Lyell, Dr. Prichard, Mr. Lawrence, and others, for the history of the discussion, and for the grounds of the decision; and I shall quote

briefly the main points and conclusions to which

nquiry has led.

balance of physiological authority, that there is a city in all species to accommodate themselves, to tain extent, to a change of external circumstances; extent varying greatly according to the species. In may thus arise changes of appearance or structure, and some of these changes are transmissible to offspring: but the mutations thus superinduced governed by constant laws, and confined within in limits. Indefinite divergence from the original is not possible, and the extreme limit of possible tion may usually be reached in a brief period of in short, species have a real existence in nature, a transmutation from one to another does not

ting all the differences of size, appearance, and is, which we find in the dogs of various races and tries, and though we have (in the Egyptian imies) skeletons of this animal as it existed three and years ago, the relation of the bones to each remains essentially the same; and, with all the tries of their shape and size, there are characters in resist all the influences both of external nature, aman intercourse, and of time.

Sect. 4.—Hypothesis of Progressive Tendencies.

ms certain limits, however, as we have said, mal circumstances produce changes in the forms iganized beings. The causes of change, and the and limits of their effects, as they obtain in the ing state of the organic creation, are in the est degree interesting. And, as has been already nated, the knowledge thus obtained, has been led with a view to explain the origin of the exist-

ing population of the world, and the succession of me past conditions. But those who have attempted such an explanation, have found it necessary to assume certain additional laws, in order to enable themselves to deduce, from the tenet of the transmutability of the species of organized beings, such a state of things as we see about us, and such a succession of states M is evidenced by geological researches. And here. again, we are brought to questions of which we must seek the answers from the most profound physiologists. Now referring, as before, to those which appear to be the best authorities, it is found that these additional positive laws are still more inadmissible than the primary assumption of indefinite capacity of change. For example, in order to account, on this hypothesia, for the seeming adaptation of the endowments of animals to their wants, it is held that the endowments are the result of the wants,—that the swiftness of the antelope, the claws and teeth of the lion, the trunk of the elephant, the long neck of the giraffe, have been produced by a certain plastic character in the constitution of animals, operated upon, for a long course of ages, by the attempts which these animals made to attain objects which their previous organization did not place within their reach. In this way, it is maintained that the most striking attributes of animals, those which apparently imply most clearly the providing skill of their Creator, have been brought forth by the long-repeated efforts of the creatures to attain the object of their desire; thus animals with the highest endowments have been gradually developed from ancestral forms of the most limited organization: thus fish, birds, and beasts, have grown from small gelatinous bodies, 'petits corps gelatineux,' possessing some obscure principle of life, and the capacity of developement, and thus man himself, with all his intellectual and moral, as well as physical privileges, has been derived from some creature of the ape or baboon tribe, urged by a constant tendency to improve, or at least to alter his condition.

As we have said, in order to arrive, even hypo-

ally, at this result, it is necessary to assume, a mere capacity for change, other positive and principles, some of which we may notice. Thus, met have, as the direct productions of nature on hypothesis, certain monads or rough draughts, the by ruliments of plants and animals. We must in these, a constant lendency to progressive immond, to the attainment of higher powers and ties than they possess; which tendency is again causely modified and controlled by the force of mal circumstances. And in order to account for conditaneous existence of animals in every stage is imaginary progress, we must suppose that is compelled to be constantly producing those centary beings, from which all animals are succesr developed.

part of this scheme is; and how complex its mamy would be, even if it did account for the facts, my be sufficient to observe, as others have done, the capacity of change, and of being influenced by mal circumstances, such as we really find it in re, and therefore such as in science we must repreit, is a tendency, not to improve, but to deteriorate. In species are modified by external causes, they illy degenerate, and do not advance. And there is estance of a species acquiring an entirely new faculty, or organ, in addition to, or in the place

hat it had before.

ories in itself disproved by the best physiological mings, but the additional assumptions which are laite, to enable its advocates to apply it to the mation of the geological and other phenomena of arth, are altogether gratuitous and fantastical.

ination of the discussions which have taken place in subject. Yet in certain speculations, occasioned discovery of the Sivatherrum, a new fossil annual.

⁷ Lyell, B. 111. 6. lv. 1 f

from the Sub-Himalaya mountains of India, M. Geoffor Saint-Hilaire speaks of the belief in the mmutability of species as a conviction which is fading away from men's minds. He speaks too of the termination of the age of Cuvier, 'la clôture du siècle de Cuvier,' aut of the commencement of a better zoological philosophy! But though he expresses himself with great animation, I do not perceive that he adduces, in support of he peculiar opinions, any arguments in addition to these which he urged during the lifetime of Cuvier. And the reader may recollect that the consideration of that controversy led us to very different anticipations from his, respecting the probable future progress of phys-The discovery of the Sivatherium supplies no particle of proof to the hypothesis, that the existing apecies of animals are descended from extinct creature which are specifically distinct: and we cannot act more wisely than in listening to the advice of that eminent naturalist, M. de Blainville. 10 'Against the hypothesis, which, up to the present time, I regard purely gratuitous, and likely to turn geologists out of the sound and excellent road in which they now are, I willingly raise my voice, with the most absolute conviction of being in the right.'

[2nd Ed.] [The hypothesis of the progressive development of species has been urged recently, in connexion with the physiological tenet of Tiedemann and De Serres, noticed in B. XVII. c. vii. sect. 3;—namely, that the embryo of the higher forms of animals passes by gradations through those forms which are permanent in inferior animals. Assuming this tenet as exact, it has been maintained that the higher animals which are found in the more recent strata may have been produced by an ulterior development of the lower forms in the embryo state; the circumstances being such as to favour such a development. But all the best physiologists agree in declaring that such an extraordinary development of the embryo is inconsistent with physiological possibility. Even if the progression

⁸ Compte Readu de l'Ac ad des Sc 1837, No. 3, p. 81.

See B. XVII C. vil. 10 Compte Readu, 1817, No. 5, p. 168.

the embryo in time have a general correspondence to the order of animal forms as more or less perfectly anized, (which is true in an extremely incomplete inexact degree,) this correspondence must be concred, not as any indication of causality, but as one those marks of universal analogy and symmetry ich are stamped upon every part of the creation.

In Lyell 11 notices this doctrine of Tiedemann and Serres; and observes, that though nature presents us in cases of animal forms degraded by incomplete delopement, she offers none of forms exalted by extraorty developement. Mr. Lyell's own hypothesis of the production of new species upon the earth, not having physiological basis, hardly belongs to this chapter.

Sect. 5 .- Question of Creation as related to Science.

traince we reject the production of new species by tens of external influence, do we then, it may be ked, accept the other side of the dilemma which we we stated; and admit a series of creations of species, some power beyond that which we trace in the ordi-

cy course of nature?

To this question, the history and analogy of science, conceive, teach us to reply as follows:—All pake-clogical sciences, all speculations which attempt to send from the present to the remote past, by the chain causation, do also, by an inevitable consequence, urge to look for the beginning of the state of things which a thus contemplate; but in none of these cases have been able, by the aid of science, to arrive at a ginning which is homogeneous with the known course events. The first origin of language, of civilization, law and government, cannot be clearly made out by asoning and research, just as little, we may expect, all a knowledge of the origin of the existing and etinct species of plants and animals, be the result of hysiological and geological investigation.

But, though philosophers have never yet demonrated, and perhaps never will be able to demonstrate,

¹¹ Principles, B 111, 0, 1v.

what was that primitive state of things in the material worlds, from which the progressive its first departure; they can still, in all the research to which we have referred, go very -determine many of the remote circumstant past sequence of events, -- ascend to a por from our position at least, seems to be near 🖠 -and exclude many suppositions respecting itself. Whether, by the light of reason alone ever be able to do more than this, it is difficult It is, I think, no irrational opinion, even on of philosophical analogy alone, that in all thou which look back and seek a beginning of thing be unable to arrive at a consistent and defini without having recourse to other grounds of well as to historical research and scientifio re When our thoughts would apprehend steadily tion of things, we find that we are obliged to up other ideas than those which regulate the scientific truths;—to call in other powers to which we refer natural events, it cannot, considered as very surprizing, if, in this parinquiry, we are compelled to look for other ordinary evidence of science.

Geology, forming one of the palætiological sciences, which trace back the history of the its inhabitants on philosophical grounds, is ciated with a number of other kinds of research are concerned about language, law, art, and conabout the internal faculties of man, his thou social habits, his conception of right, his love of Geology being thus brought into the atmosphis moral and mental speculations, it may be experi her investigations of the probable past will influence common to them; and that she will allowed to point to an origin of her own, physical beginning of things; but that, as proaches towards such a goal, she will be led that it is the origin of many trains of events, 🕍 of convergence of many lines. It may be, that of being allowed to travel up to this focus of hi

tre only able to estimate its place and nature, and to form of it such a judgment as this;—that it is not only the source of mere vegetable and animal life, but also of rational and social life, language and arts, law and order; in short, of all the progressive tendencies by which the highest principles of the intellectual and moral world have been and are developed, as well as of the succession of organic forms, which we find scattered, dead or living, over the earth.

This reflection concerning the natural scientific view of creation, it will be observed, has not been sought for, from a wish to arrive at such conclusions; but it has flowed spontaneously from the manner in which we have had to introduce geology into our classification of the sciences: and this classification was framed from an unbiassed consideration of the general analogies and guiding ideas of the various portions of our knowledge. Such remarks as we have made may on this account be

considered more worthy of attention.

But such a train of thought must be pursued with caution. Although it may not be possible to arrive at a right conviction respecting the origin of the world, without having recourse to other than physical considerations, and to other than geological evidence, yet extraneous considerations, and extraneous evidence. respecting the nature of the beginning of things, must never be allowed to influence our physics or our geology. Our geological dynamics, like our astronomical dynamics, may be inadequate to carry us back to an origin of that state of things, of which it explains The progress: but this deficiency must be supplied, not by adding supernatural to natural geological dynamics, but by accepting, in their proper place, the views supplied by a portion of knowledge of a different character and order. If we include in our Theology the speculations to which we have recourse for this purpose, we must exclude them from our Goology. The two sciences may conspire, not by having any part in common; but because, though widely diverse in their lines, both point to a mysterious and invisible origin of the world.

AH that which claims our assent on those higher

grounds of which theology takes cognizance, must due such assent as is consistent with those grounds, that a it must require belief in respect of all that bears of a the highest relations of our being, those on whom depend our duties and our hopes. Doctrines of that kind may and must be conveyed and maintained by means of information concerning the past history (man, and his social and material, as well as moral ad spiritual fortunes. He who believes that a Providence has ruled the affairs of mankind, will also believe that a Providence has governed the material world. But any language in which the narrative of this government of the material world can be conveyed, mist necessarily be very imperfect and inappropriate, being expressed in terms of those ideas which have been selected by men, in order to describe the appearances and relations of created things as they affect one another. In all cases, therefore, where we have to attempt to interpret such a narrative, we must feel il at we are extremely hable to err; and most of all, when our interpretation refers to those material of jects and operations which are most foreign to the main purpose of a history of providence. If we have to consider communication containing a view of such a government of the world, imparted to us, as we may suppose, in order to point out the right direction for our feelings of trust, and reverence, and hope, towards the Governor of the world, we may expect that we shall be in no danger of collecting from our authority erroncous notions with regard to the power, and wisdom, and goodness of His government, or with respect to our own place, duties, and prospects, and the history of our race so far as our duties and prospects are concerned But that we shall rightly understand the detail of all events in the history of man, or of the skies, or of the earth, which are narrated for the purpose of thus going a right direction to our minds, is by no means equally certain; and I do not thank it would be too much to say, that an immunity from perplexity and errour, is such matters, is, on general grounds, very improbable It cannot then surprize us to find, that parts of such

stions which seem to refer to occurrences like those lich astronomers and geologists have attempted to mine the laws, have given rise to many interprene, all inconsistent with one another, and most of at variance with the best established principles

conomy and geology. may be urged, that all truths must be consistent all other truths, and that therefore the results of geology or astronomy cannot be irreconcileable the statements of true theology. And this uniconsistency of truth with itself must be assented at it by no means follows that we must be able tain a full insight into the nature and manner of a consistency. Such an insight would only be ble if we could obtain a clear view of that central of truth, the source of the principles which appear separate lines of speculation. To expect that ould see clearly how the providential government world is consistent with the unvarying laws by its motions and developements are regulated, is meet to understand thoroughly the laws of motion, svelopement, and of providence; it is to expect we may ascend from geology and astronomy to the eve and legislative center, from which proceeded and stars; and then descend again into the moral piritual world, because its source and center are ame as those of the material creation. It is to hat reason, whether finite or infinite, must be conat with itself; and that, therefore, the finite must is to comprehend the infinite, to travel from any province of the moral and material universe to ther, to trace their bearing, and to connect their daries.

the of the advantages of the study of the history that re of science in which we are now engaged is, is warns us of the hopeless and presumptuous charoff such attempts to understand the government is world by the aid of science, without throwing facredit upon the reality of our knowledge;—that it shows how solid and certain each science is, so it refers its own facts to its own ideas, it con-

fines each science within its own limits, and on it as empty and helpless, when it pronounces up subjects which are extraneous to it. The empersons who should seek a geological narrative logical records, would be rather in the search its in their interpretation of what they might find; like manner the errour of those who would a against a supernatural beginning, or a providerection of the world, upon geological or physical reasonings, would be, that they had expects sciences alone to place the origin or the governments of the world in its proper light.

Though these observations apply generally to palætiological sciences, they may be permitted because they have an especial bearing upon some difficulties which have embarrassed the progeological speculation; and though such difficult I trust, nearly gone by, it is important for un

them in their true bearing.

From what has been said, it follows that geolic astronomy are, of themselves, incapable of given any distinct and satisfactory account of the the universe, or of its parts. We need not then, at any particular instance of this incapaci for example, that of which we have been speaking impossibility of accounting by any natural me the production of all the successive tribes of plan animals which have peopled the world in the stages of its progress, as geology teaches us. The were, like our own animal and vegetable con raries, profoundly adapted to the condition in they were placed, we have ample reason to belie when we inquire whence they came into this out geology is silent. The mystery of creation is not the range of her legitimate territory; she says 📸 but she points upwards.

Sect. 6.—The Hypothesis of the regular Creat. Extinction of Species.

1. Creation of Species.—We have already authorable, as a physiological doctrine, is the

the transmutability and progressive tendency of cies; and therefore, when we come to apply to pretical geology the principles of the present chapter, portion of the subject will easily be disposed of. ardly know whether I can state that there is any er principle which has been applied to the solution the geological problem, and which, therefore, as a neral truth, ought to be considered here. Mr. Lyell, leed, has spoken12 of an hypothesis that 'the sucrive creation of species may constitute a regular et of the economy of nature:' but he has nowhere, I ink, so described this process as to make it appear what department of science we are to place the pothesis. Are these new species created by the prototion, at long intervals, of an offspring different in prices from the parents? Or are the species so ated produced without parents? Are they graally evolved from some embryo substance? or do by suddenly start from the ground, as in the creation the poet?

Limbed and full-grown out of the ground up rose

As from his lair, the wild beast where he wons
In forest wild, in thicket, brake, or den . . .

The grassy clods now calved , now half appeared
The tawny lion, pawing to get free
His hinder parts; then springs as broke from bounds,
And rampant shakes his brinded mane, &c. &c.

Paradise Lost, B. vii.

Some selection of one of these forms of the hyponia, rather than the others, with evidence for the section, is requisite to entitle us to place it among the own causes of change which in this chapter we are raidering. The bare conviction that a creation of mies has taken place, whether once or many times, long as it is unconnected with our organical sinces, is a tenet of Natural Theology rather than of psical Philosophy.

[Mr. Lyell has explained his theory] by

supposing man to people a great desert, introducing into it living plants and animals; and he has traced in a very interesting manner, the results of such a hypothesis on the distribution of vegetable and animal species. But he supposes the agents who this, before they import species into particular loslities, to study attentively the climate and other physical conditions of each spot, and to use various precautions. It is on account of the notion of desagn thus introduced that I have, above, described thu opinion as rather a tenet of Natural Theology than of Physical Philosophy.

Mr. Edward Forbes has published some highly interesting speculations on the distribution of existing species of animals and plants. It appears that the manner in which animal and vegetable forms are now diffused requires us to assume centers from which the diffusion took place by no means limited by the present divisions of continents and Islands. The changes of land and water which have thus occurred since the existing species were placed on the earth must have been very extensive, and perhaps reach into the glacial period of

which I have spoken above.14

According to Mr. Forbes's views, for which he has offered a great body of very striking and converging reasons, the present vegetable and animal population of the British Isles is to be accounted for by the following series of events. The marine deposits of the meiocene formation were elevated into a great Atlantic continent, yet separate from what is now America, and having its western shore where now the great semicircular belt of gulf-weed ranges from the 15th to the 45th parallel of latitude. This continent then became stocked with life, and of its vegetable population, the flora of the west of Ireland, which has many points in

14 See, in Memoirs of the Geolo- existing Fauna and Flora of the gioni Survey of Great Britain, British Isles, and the Geological vol. i. p 336, Professor Forbes s Changes which have affected their

Memoir On the Connexion be area, especially during the special tween the Distribution of the of the Northern Drift."

common with the flora of Spain and the Atlantic Lalands (the Asturian flora), is the record. The region between Spain and Ireland, and the rest of this meiocene continent, was destroyed by some geological movement, but there were left traces of the connexion which still remain. Eastwards of the flora just mentioned, there is a flora common to Devon and Cornwall, to the south-east part of Ireland, the Channel Lsles, and the adjacent provinces of France;—a flora passing to a southern character; and having its course marked by the remains of a great rocky barrier, the destruction of which probably took place anterior to the formation of the narrower part of the channel. Eastward from this Devon or Norman flora, again, we have the Kentish flora, which is an extension of the flora of North-western France, insulated by the breach which formed the straits of Dover. Then came the Glacial period, when the cast of England and the north of Europe were submerged, the northern drift was distributed, and Eugland was reduced to a chain of islands or ridges, formed by the mountains of Wales, Cumberland, and Scotland, which were connected with the land of Scandinavia. This was the period of glaciers, of the dispersion of boulders, of the grooving and scratching of rocks as they are now found. The climate being then much colder than it now is, the flora, even down to the water's edge, consisted of what are now Alpine plants; and this Alpine flora is common to Scandinavia and to our mountain-summits. And these plants kept their places, when, by the clevation of the land, the whole of the present German Ocean became a continent connecting Britain with central Europe. For the increased elevation of their stations counterbalanced the diminished cold of the succeeding period. Along the dry hed of the German Sea, thus elevated, the principal part of the existing flora of England, the Germanic flora, migrated. A large portion of our existing animal population also came over through the same region, and along with those, came hyenas, tigers, rhinoceros, aurochs, elk, wolves, beavers, which are extinct in Britain, and other animals which are extinct altogether, as the primigenian elephant or mammoth. But then agua the German Ocean and the Irish Channel were scooped out; and the chinate again changed. In our plana so detached, many of the larger beasts perished, seltheir bones were covered up in peat-mosses and caus where we find them. This distinguished nature a has further shown that the population of the sea leads itself to the same view. Mr. Forbes says that the writings of Mr Smith, of Jordan hill, 'On the last Changes in the relative Levels of the Land and Sea in the British Islands, published in the Memoirs of the Wernerian Society for 1837-8, must be esteemed the foundation of a critical investigation of this subject in

Britain.

2. Extinction of Species .- With regard to the extinction of species, Mr. Lyell has propounded a doctrace which is deserving of great attention here. Brocchi, when he had satisfied himself, by examination of the Sub-Apennines, that about half the species which had lived at the period of their deposition, had since become extinct, suggested as a possible cause for this occurrence, that the vital energies of a species, like that of an individual, might gradually decay in the progress of time and of generations, till at last the prolific power might fail, and the species wither away. Such a property would be conceivable as a physiclogical fact; for we see something of the kind in fruit-trees propagated by cuttings: after some time, the stock appears to wear out, and loses its peculiar qualities. But we have no sufficient evidence that this is the case in generations of creatures continued by the reproductive powers. Mr. Lyell conceives, that, without admitting any inherent constitutional tendency to deteriorate, the misfortunes to which plants and animals are exposed by the change of the physical circumstances of the earth, by the alteration of land and water, and by the changes of climate, must very frequently occasion the loss of several species. We have historical evidence of the extinction of one conspicuous species, the Dodo, a bird of large size and

ther form, which inhabited the Isle of France that island was first discovered, and which now onger exists. Several other species of animals plants seem to be in the course of vanishing from ce of the earth, even under our own observation. taking into account the greater changes of the the of the globe which geology compels us to me, we may imagine many or all the existing of hving things to be extirpated. mce, that reduction of the climate of the earth appears, from geological evidence, to have taken already, be supposed to go on much further, dvancing snow and cold of the polar regions may by the greater part of our plants and animals, drive the remainder, or those of them which the requisite faculties of migration and accomation, to seek an asylum near the equator. And suppose the temperature of the earth to be still per reduced, this zone of now-existing life, having ather place of refuge, will perish, and the whole will be tenanted, if at all, by a new creation. recauses might produce the same effect as a change limate; and, without supposing such causes to the whole globe, it is easy to imagine circumbes such as might entirely disturb the equilibrium a the powers of diffusion of different species have aced, -might give to some the opportunity of ding and conquering the domain of others; and e end, the means of entirely suppressing them. establishing themselves in their place. at this extirpation of certain species, which, as

mstances, might happen upon a greater scale, if tange of external changes were to be much end, cannot be doubted. The extent, therefore, to he natural causes may account for the extinction pecies, will depend upon the amount of change he we suppose in the physical conditions of the lit must be a task of extreme difficulty to take the effect upon the organic world, even if the local circumstances were given. To determine the

physical condition to which a given state of the earth would give rise, I have already noted as another very difficult problem. Yet these two problems must be solved, in order to enable us to judge of the sufficiency of any hypothesis of the extinction of species, and a the mean time, for the mode in which new spens come into the places of those which are extinguished, we have (as we have seen) no hypothesis which physiology can, for a moment, sanction.

Sect. 7 .- The Imbedding of Organic Remains.

THERE is still one portion of the Dynamics of Geologie a branch of great and manifest importance, which I have to notice, but upon which I need only spek very briefly. The mode in which the spoils of existing plants and animals are imbedded in the deposits now forming, is a subject which has naturally attracted the attention of geologists. During the controversy which took place in Italy respecting the fossils of the Sub-Apennine hills, Vitaliano Donati, 15 in 1750, undertook an examination of the Adriatic, and found that deposit containing shells and corals, extremely resembling the strata of the hills, were there in the act of formatica But without dwelling on other observations of lat kind, I may state that Mr. Lyell has treated the subject, and all the topics connected with it, in a very full and satisfactory manner. He has explained, 18 by an excellent collection of illustrative facts, how deposit of various substance and contents are formed, how plants and animals become fossil in peat, in bleve sand, in volcanic matter, in alluvial soil, in caves and in the beds of lakes and seas. This exposition is d the most instructive character, as a means of obtaining right conclusions concerning the causes of geological phenomena. Indeed, in many cases, the similarity of past effects with operations now going on, is so complete, that they may be considered as identical; and

ORGANIC GEOLOGICAL DYNAMICS,

495

discussion of such cases belongs, at the same time, seological Dynamics and to Physical Geology; just be problem of the fall of meteorolites may be consed as belonging alike to mechanics and to physical momy. The growth of modern peat-mosses, for mple, fully explains the formation of the most ient: objects are buried in the same manner in the tions of active and of extinct volcanoes; within limits of history, many estuaries have been filled and in the deposits which have occupied these les, are strata containing shells, 17 as in the older pations.

Tyell, B. m. c. zvil. p. 286. See also his Address to the Geoloi Society in 1837, for an account of the Researches of Mr. Stokes of Professor Göppert, on the lapidification of vegetables.

PHYSICAL GEOLOGY.

CHAPTER VIL

PROGRESS OF PHYSICAL GEOLOGY.

Sect. 1.—Object and Distinctions of Physical Geology.

BEING, in consequence of the steps which we have attempted to describe, in possession of two sources, one of which traces the laws of action of known causes, and the other describes the phenomena which the earth's surface presents, we are now prepared to examine how far the attempts to refer the facts to their causes have been successful: we are ready to enter upon the consideration of Theoretical or *Physical* Geology, as, by analogy with Physical Astronomy, we

may term this branch of speculation.

The distinction of this from other portions of our knowledge is sufficiently evident. In former times, Geology was always associated with Mineralogy, and sometimes confounded with it; but the mistake of such an arrangement must be clear, from what has been said. Geology is connected with Mineralogy, only so far as the latter science classifies a large portion of the objects which Geology employs as evidence of its statements. To confound the two is the same errour as it would be to treat philosophical history as identical with the knowledge of medals. Geology procures evidence of her conclusions wherever she can, from minerals or from seas; from inorganic or from organic bodies; from the ground or from the skies. The geologist's business is to learn the past history of the earth; and he is no more limited to one or a few kinds of documents, as his sources of information.

the historian of man, in the execution of a

cal Geology, of which I now speak, may not a easily separable from Descriptive Geology: they have generally been combined, for few sen content to describe, without attempting measure to explain. Indeed, if they had done probable that their labours would have been zealous, and their expositions far less im-

we by no means regret, therefore, the of these two kinds of knowledge, which has occurred; but still, it is our business to separate. The works of astronomers, before the ound physical astronomy, were full of theories, were advantageous, not prejudicial, to the of the science.

gical theories have been abundant and various; our history of them must be brief. For our , as must be borne in mind, to exhibit these, far as they are steps discoverably tending to theory of the earth: and in most of them we race this character. Or rather, the portions of curs of geologists which do merit this praise, to the two preceding divisions of the subject, as been treated of there.

towards a science as real and stable as those we have already treated of (and this is the form have ought to trace it), hitherto consists of few We hardly know whether the progress is begun, story of Physical Astronomy almost commences ewton, and few persons will venture to assert a Newton of Geology has yet appeared.

some examination of the attempts which have ade is requisite, in order to explain and justify w which the analogy of scientific history leads take, of the state of the subject. Though far stending to give even a sketch of all past geolopeculations. I must notice some of the forms eculations have at different times assumed,

\$11.

Sect. 2.—Of Fanciful Geological Opinions.

REAL and permanent geological knowledge, like all other physical knowledge, can be obtained only by inductions of classification and law from many clearly seen phenomena. The labour of the most active, the talent of the most intelligent, are requisite for such a purpose. But far less than this is sufficient to put in busy operation the inventive and capricious fancy. A few appearances hastily seen, and arbitrarily interpreted, are enough to give rise to a wondrous tale of the past, full of strange events and supernatural agencies. The mythology and early poetry of nations afford sufficient evidence of man's love of the wonderful, and of his inventive powers, in early stages of intellectual developement. The scientific faculty, on the other hand, and especially that part of it which is requisite for the induction of laws from facts, emerges slowly and with difficulty from the crowd of adverse influences, even under the most favourable circumstances. We have seen that in the ancient world, the Greeks alone showed themselves to possess this talent: and what they thus attained to, amounted only to a few sound doctrines in astronomy, and one or two extremely imperfect truths in mechanics, optics, and music, which their successors were unable to retain. No other nation, till we come to the dawn of a better day in modern Europe, made any positive step at all in sound physical speculation. Empty dreams or useless exhibitions of ingenuity, formed the whole of their essays at such knowledge.

It must, therefore, independently of positive evidence, be considered as extremely improbable, that any of these nations should, at an early period, have arrived, by observation and induction, at wide general truths, such as the philosophers of modern times have only satisfied themselves of by long and patient labour and thought. If resemblances should be discovered between the assertions of ancient writers and the discoveries of modern science, the probability in all cases, the cor-

in most, is, that these are accidental coincithat the ancient opinion is no anticipation smodern discovery, but is one guess among many, whit the more valuable because its expression with a truth. The author of the guess could tend the truth, because his mind was not prepared aprehend it. Those of the ancients who spoke carmony which binds all things together, could ean the Newtonian gravitation, because they had been led to conceive an attractive force, governed finite mathematical laws in its quantity and tion.

agreement with these views, we must, I conceive, ate the opinions which we find among the ancients, ting the changes which the earth's surface has gone. These opinions, when they are at all of a lakind, are arbitrary fictions of the fancy, showing love of generality indeed, but indulging it withhat expense of labour and thought which alone ander it legitimate.

might, therefore, pass by all the traditions and lations of Oriental, Egyptian, and Greek cosmona extraneous to our subject. But since these recently been spoken of, as conclusions collected, per vaguely, from observed facts, we may make

ark or two upon them.

e notion of a series of creations and destructions rids, which appears in the sacred volume of the cos, which formed part of the traditionary lore of t, and which was afterwards adopted into the y and philosophy of Greece, must be considered mythological, not a physical, doctrine. When tostrine was dwelt upon, men's thoughts were ted, not to the terrestrial facts which it seemed to in, but to the attributes of the deities which it rated. The conception of a Supreme power, ling and guiding the progress of events, which is anent among all perpetual change, and regular g all seeming chance, was readily entertained by

Lyell, B. r c ii p. S. 4th ada

contemplative and enthusiastic minds; and when nature phenomena were referred to this doctrine, it was rated for the purpose of fastening its impressivenes upt the senses, than in the way of giving to it author " and support. Hence we perceive that in the exposit a of this doctrine, an attempt was always made to the and elevate the mind with the notions of marve by events, and of infinite times, in which vast cycles of order recurred. The 'great year,' in which all celestal phenomena come round, offered itself as capable of being calculated; and a similar great year was readly assumed for terrestrial and human events there were to be brought round by great cycles wit only deluges and conflagrations which were to destry and renovate the earth, but also the series of historical occurrences. Not only the sea and land were to recommence their alternations, but there was to be another Argo, which should carry warriors on the first seaforay," and another succession of heroic wars. Looking at the passages of ancient authors which refer to terrestrial changes in this view, we shall see that they are addressed almost entirely to the love of the marvellous and the infinite, and cannot with propriety be taken as indications of a spirit of physical philosophy. For example, if we turn to the celebrated passage in Ovid," where Pythagoras is represented as asserting that land becomes sea, and sea land, and many other changes which geologists have verified, we find that these observations are associated with many fables, as being matter of exactly the same kind, -the fountain of Ammon which was cold by day and warm by night 4 - the waters of Salmacis which efferminate men;-the Clitorian spring which makes them loathe wine;—the Simplegades islands which were once moveable; the Tritonian lake which covered men's bodies with feathers; - and many similar marvels. And the general purport of the whole is, to countenance the doctrine of the metempsychosis, and the Prthagorean injunction of not eating animal food. It is

Virg. Relog. 4.

dered as having been contemplated rather in the

pirit of poetry than of science.

We must estimate in the same manner, the very markable passage brought to light by M. Elie de leaumont, from the Arabian writer, Kazwiri; in thich we have a representation of the same spot of round, as being, at successive intervals of five hundred wars, a city, a sea, a desert, and again a city. This avention is adduced, I conceive, rather to feed the opetite of wonder, than to fix it upon any reality: as he title of his book, The Marvels of Nature, obviously atimates.

The speculations of Aristotle, concerning the exchanges of land and sea which take place in long periods, are not formed in exactly the same spirit, but hey are hardly more substantial; and seem to be quite arbitrary, since they are not confirmed by any exsimples and proofs. After stating that the same spots of the earth are not always land and always water, he rives the reason. 'The principle and cause of this is,' he says, 'that the inner parts of the earth, like the bodies of plants and animals, have their ages of vigour and of decline; but in plants and animals all the parts we in vigour, and all grow old, at once : in the earth different parts arrive at maturity at different times by the operation of cold and heat: they grow and decay on account of the sun and the revolution of the stars, and thus the parts of the earth acquire different power, so that for a certain time they remain moist, and then become dry and old: and then other places are revivised, and become partially watery.' We are, I conceive, doing no injustice to such speculations by classing them among fanciful geological opinions.

We must also, I conceive, range in the same division another class of writers of much more modern times;

I mean those who have framed their geology by interpretations of Scripture. I have already endeavoured to show that such an attempt is a perver-

⁴ Ann. des Sc. Nat. xxv. 380.

Meteorol, I. 14.

cannot lead to any physical truth. I do not here speak of geological speculations in which the Mosac account of the deluge has been referred to; for whatever errours may have been committed on that subject, it would be as absurd to disregard the most ancient historical record, in attempting to trace back the history of the earth, as it would be, gratuitously to reject any other source of information. But the interpretations of the account of the creation have gone further beyond the limits of sound philosophy: and when we look at the arbitrary and fantastical inventions by which a few phrases of the writings of Moses have been moulded into complete systems, we cannot doubt that these interpretations belong to the present Section.

I shall not attempt to criticize, nor even to enumerate, these Scriptural Geologies,—Sacred Theories of the Earth, as Burnet termed his. Ray, Woodward, Whiston, and many other persons to whom science has considerable obligations, were involved, by the speculative habits of their times, in these essays; and they have been resumed by persons of considerable talent and some knowledge, on various occasions up to the present day; but the more geology has been studied on its own proper evidence, the more have geologists seen the unprofitable character of such

labours.

I proceed now to the next step in the progress of Theoretical Geology.

Sest. 3 .- Of Premature Geological Theories.

While we were giving our account of Descriptive Geology, the attentive reader would perceive that we did, in fact, state several steps in the advance towards general knowledge; but when, in those cases, the theoretical aspect of such discoveries softened into an appearance of mere classification, the occurrence was assigned to the history of Descriptive rather than of Theoretical Geology. Of such a kind was the establishment, by a long and vehement controversy, of the fact,

that the impressions in rocks are really the traces of succent living things; such, again, were the division of rocks into Primitive, Secondary, Tertiary; the accertainment of the orderly succession of organic remains; the consequent fixation of a standard series of formations and strata; the establishment of the igneous nature of trap rocks; and the like. These are geological truths which are assumed and implied in the very language which geology uses; thus showing how in this, as in all other sciences, the succeeding steps involve the preceding. But in the history of geological theory, we have to consider the wider attempts to combine the facts, and to assign them to their causes.

The close of the last century produced two antagonist theories of this kind, which long maintained a fierce and doubtful struggle;—that of Werner and that of Hutton: the one termed Neptunian, from its ascribing the phenomena of the earth's surface mainly to aqueous agency; the other Plutonian or Vulcanian, because it employed the force of subterraneous fire as its principal machinery. The circumstance which is most worthy of notice in these remarkable essays is, the endeavour to give, by means of such materials as the authors possessed, a complete and simple account of all the facts of the earth's history. The Saxon professor, proceeding on the examination of a small district in Germany, maintained the existence of a chaotic fluid, from which a series of universal formations had been precipitated, the position of the strata being broken up by the falling in of subterraneous cavities, in the intervals between these depositions. The Scotch philosopher, who had observed in England and Scotland, thought himself justified in declaring that the existing causes were sufficient to spread new strate on the bottom of the ocean, and that there they are consolidated, elevated, and fractured by volcanic heat, so as to give rise to new continents.

It will hardly be now denied that all that is to remain as permanent science in each of these systems must be proved by the examination of many cases. Theories so wide and simple, were consistent only with a comparatively scanty collection of facts, and belong to the early stage of geological knowledge. In the progress of the science, the 'theory' of each part of the earth must come out of the examination of that part, combined with all that is well established concerning all the rest; and a general theory must result from the comparison of all such partial theoretical views. Any attempt to snatch it before its time must fail; and therefore we may venture at present to designate general theories, like those of Hutton and Werner, as premature.

This, indeed, is the sentiment of most of the good geologists of the present day. The time for such general systems, and for the fierce wars to which the opposition of such generalities gives rise, is probably now past for ever; and geology will not again witness such a controversy as that of the Wernerian and Huttonian

schools.

With heaven's artillery fraught, come rattling on Over the Caspian: then stand front to front, Hovering a space, till winds the signal blow. To join their dark encounter in mid air. So frowned the mighty combatants, that hell Grew darker at their frown; so matched they stood: For nover but once more was either like. To meet so great a foc.

The main points really affecting the progress of sound theoretical geology, will find a place in one of the two next Sections.

[2nd Ed.] [I think I do no injustice to Dr. Hutton in describing his theory of the earth as premature. Prof. Playfair's elegant work, Illustrations of the Huttonian Theory, (1802), so justly admired, contains many doctrines which the more mature geology of modern times rejects; such as the igneous origin of chalk-flints, siliceous puddingstone, and the like; the universal formation of river-heds by the rivers themselves; and other points. With regard to this last-mentioned

PROGRESS OF PHYSICAL GEOLOGY. 505

question, I think all who have read Deluc's Geologie (1810) will deem his refutation of Playfair complete.

But though Hutton's theory was premature, as well as Werner's, the former had a far greater value as an important step on the road to truth. Many of its boldest hypotheses and generalizations have become a part of the general creed of geologists; and its publication is perhaps the greatest event which has yet occurred in the progress of Physical Geology.]

CHAPTER VIII.

THE TWO ANTAGONIST DOCTRINES OF GEOLOGY.

Sect. 1 .- Of the Doctrine of Geological Catastrophes.

THAT great changes, of a kind and intensity quite different from the common course of events, and which may therefore properly be called catastrophes, have taken place upon the earth's surface, was an opinion which appeared to be forced upon men by obvious facts. Rejecting, as a mere play of fancy, the notions of the destruction of the earth by cataclysias or conflagrations, of which we have already spoken, we find that the first really scientific examination of the materials of the earth, that of the Sub-Apennine hills led men to draw this inference. Leonardi da Vinci. whom we have already noticed for his early and strenuous assertion of the real marine origin of fossil impressions of shells, also maintained that the bottom of the sea had become the top of the mountain; yet his mode of explaining this may perhaps be claimed by the modern advocates of uniform causes, as more allied to their opinion, than to the doctrine of catastrophes. But Steno, in 1669, approached nearer to this doctrine; for he asserted that Tuscany must have changed its face at intervals, so as to acquire six different configurations, by the successive breaking down of the older strata into inclined positions, and the horizontal deposit of new ones upon them. Strabo, indeed, at an earlier period had recourse to earthquakes, to explain the occurrence of shells in mountains; and Hooke published the same opinion later. But the Italian geologists prosecuted their researches under the advantage of having.

I 'Here is a part of the earth center, and what was the bottom which has become more light, and of the sea is become the top of the which rises, while the opposite mountain.'—Venturi's Léonard de part approaches nearer to the Pinci.

se at hand, large collections of conspicuous and conent phenomena. Lazzaro Moro, in 1740, attempted apply the theory of earthquakes to the Italian strata; both he and his expositor, Cirillo Generelli, inclined her to reduce the violence of these operations within ordinary course of nature,2 and thus leant to the trine of uniformity, of which we have afterwards to Moro was encouraged in this line of speculation the extraordinary occurrence, as it was deemed by persons, of the rise of a new volcanic island from pep part of the Mediterranean, near Santorino, in But in other countries, as the geological facts to studied, the doctrine of catastrophes appeared to ground. Thus in England, where, through a large s of the country, the coal-measures are extremely fined and contorted, and covered over by more horihal fragmentary beds, the opinion that some violent etrophe had occurred to dislocate them, before the crincumbent strata were deposited, was strongly It was conceived that a period of violent and deactive action must have succeeded to one of repose; that, for a time, some unusual and paroxysmal bee must have been employed in elevating and breakthe pre-existing strata, and wearing their fragments amooth pebbles, before nature subsided into a new of tranquillity and vitality. In like manner Cuvier, the alternations of fresh-water and salt-water cies in the strata of Paris, collected the opinion of ries of great revolutions, in which 'the thread of action was broken.' Deluc and others, to whom we the first steps in geological dynamics, attempted efully to distinguish between causes now in action, those which have ceased to act; in which latter they reckoned the causes which have elevated the iting continents. This distinction was assented to many succeeding geologists. The forces which have ed into the clouds the vast chains of the Pyrenees, Alps, the Andes, must have been, it was deemed,

² Lyell, i. 3. p. 64. (4th ed.)

something very different from any agencies now op-

rating.

This opinion was further confirmed by the appearance of a complete change in the forms of animal and vegetable life, in passing from one formation to another The species of which the remains occurred, were entirely different, it was said, in two successive epochs: a ter creation appears to have intervened; and it was readly believed that a transition, so entirely out of the common course of the world, might be accompanied by paroxysms of mechanical energy. Such views prevail extensively among geologists up to the present time: for instance, in the comprehensive theoretical generalizations of Em de Beaumont and others, respecting mountain-chains it is supposed that, at certain vast intervals, systems of mountains, which may be recognized by the parallelan of course of their inclined beds, have been disturbed and elevated, lifting up with them the aqueous strate which had been deposited among them in the intervening periods of tranquillity, and which are recognized and identified by means of their organic remains: and according to the adherents of this hypothesis, these sudden elevations of mountain-chains have been followed, again and again, by mighty waves, desolating whole regions of the earth.

The peculiar bearing of such opinions upon the progress of physical geology will be better understood by attending to the doctrine of uniformity, which is opposed to them, and with the consideration of which we shall close our survey of this science, the last branch

of our present task.

Sect. 2 .- Of the Doctrine of Geological Uniformity.

THE opinion that the history of the earth had involved a series of catastrophes, confirmed by the two great classes of facts, the symptoms of mechanical violence on a very large scale, and of complete changes in the living things by which the earth had been tenanted, took strong hold of the geologists of England, France, and Germany. Hutton, though he denied that there

WO ANTAGONIST DOCTRINES OF GEOLOGY. 509

evidence of a beginning of the present state of age, and referred many processes in the formation of to existing causes, did not assert that the elevaforces which raise continents from the bottom of ocean, were of the same order, as well as of the kind, with the volcanoes and earthquakes which shake the surface. His doctrine of uniformity founded rather on the supposed analogy of other of speculation, than on the examination of the ount of changes now going on. 'The Author of pare,' it was said, ' has not permitted in His works symptom of infancy or of old age, or any sign by ach we may estimate either their future or their past ration:' and the example of the planetary system referred to in illustration of this.4 And a general conssion that the champions of this theory were not posed to accept the usual opinions on the subject of ation, was allowed, perhaps very unjustly, to weigh

ongly against them in the public opinion.

While the rest of Europe had a decided bias towards doctrine of geological catastrophes, the phenomena Italy, which, as we have seen, had already tended soften the rigour of that doctrine, in the progress of eculation from Steno to Generalli, were destined to tigate it still more, by converting to the belief of iformity transalpine geologists who had been bred in the catastrophist creed. This effect was, indeed. edual. For a time the distinction of the recent and tertiary period was held to be marked and strong. roochi asserted that a large portion of the Subpenume fossil shells belonged to a hving species of Mediterranean Sea but the geologists of the rest Europe turned an incredulous car to this Italian net; and the persuasion of the distinction of the tiary and the recent period was deeply impressed on ost geologists by the memorable labours of Cuvier d Brongniart on the Paris basin. Still, as other rtiary deposits were examined, it was found that sy could by no means be considered as contemporangers, but that they formed a chain of pa advancing nearer and nearer to the recent per Above the strata of the basins of London and Par he use newer strata of Toursine of Bourdeaux, of valley a the Bormaia and the Superga near To and of the basis of Vienna explored by M. TWO ANTAGONIST DOCTRINES OF GEOLOGY. 511

had been frequently led to reflect on the precept of Descartes, that a philosopher should once in his life doubt everything he had been taught; but I still retained so much faith in my early geological creed as to feel the most lively surprize on visiting Sortino, Pentalica, Syracuse, and other parts of the Val di Note, at beholding a limestone of enormous thickness, filled with recent shells, or sometimes with mere easts of shells, resting on marl in which shells of Mediterranean species were imbedded in a high state of preservation. All idea of [necessarily] attaching a high antiquity to a regularly-stratified limestone, in which the casts and impressions of shells alone were visible, vanished at once from my mind. At the same time, I was struck with the identity of the associated igneous rocks of the Val di Noto with well-known varieties of 'trap' in Scotland and other parts of Europe; varieties which I had also seen entering largely into the structure of Etns.

'I occasionally amused myself,' Mr. Lyell adds, with speculating on the different rate of progress which geology might have made, had it been first cultivated with success at Catania, where the phenomena above alluded to, and the great elevation of the modern tertiary beds in the Val di Noto, and the changes produced in the historical era by the Calabrian earthquakes, would have been familiarly known.'

Before Mr. Lyell entered upon his journey, he had put in the hands of the printer the first volume of his Principles of Geology, being an attempt to explain the former Changes of the Earth's Surface by reference to Causes now in Operation.' And after viewing such phenomena as we have spoken of, he, no doubt, judged that the doctrine of catastrophes of a kind entirely different from the existing course of events, would never have been generally received, if geologists had at first formed their opinions upon the Sicilian strata. The boundary separating the present from the anterior state of things crumbled away; the difference of fossil and recent species had disappeared, and, at the same time, the changes of position which marine strata had

be ill excused by pleading the obligation of

appealing to known causes, 10

In truth, we know causes only by their and in order to learn the nature of the causes modify the earth, we must study them through ages of their action, and not select arbitraril period in which we live as the standard for all epochs. The torces which have produced the and the Andes are known to us by experience, a than the forces which have raised Etna to its mi height; for we learn their amount in both con their results. Why, then, do we make a me using the latter case as a measure for the former how can we know the true scale of such force, 📦 by comprehending in our view all the facts while can bring together!

In reality, when we speak of the uniform nature, are we not obliged to use the term in large sense, in order to make the doctrine at all ten It includes catastrophes and convulsions of

For in the of the Inductive Sciences, Bell

TWO ANTAGONIST DOCTRINES OF GEOLOGY. 515

riolence which we must allow to these changes? In order to enable ourselves to represent geological causes operating with uniform energy through all time, we must measure our time by long cycles, in which repose and violence alternate; how long may we extend this yele of change, the repetition of which we express by the word uniformity?

And why must we suppose that all our experience, geological as well as historical, includes more than one such cycle? Why must we insist upon it, that man has been long enough an observer to obtain the everage of forces which are changing through immen-

surable time?

The analogy of other sciences has been referred to. as sanctioning this attempt to refer the whole train of facts to known causes. To have done this, it has been mid, is the glory of Astronomy: she seeks no hidden virtues, but explains all by the force of gravitation, which we witness operating at every moment. But let us ask, whether it would really have been a merit in the founders of Physical Astronomy, to assume that the celestial revolutions resulted from any selected class of known causes! When Newton first attempted to explain the motions of the moon by the force of gravity, and failed because the measures to which he referred were erroneous, would it have been philosophical in him, to masst that the difference which he found ought to be overlooked, since otherwise we should be compelled to go to causes other than those which we usually witness in action? Or was there any praise due to those who assumed the celestial forces to be the same with gravity, rather than to those who assimilated them with any other known force, as magnetism, till the calculation of the laws and amount of these forces, from the celestial phenomena, had clearly sanctioned such an identification? We are not to select a conclusion now well proved, to persuade ourselves that it would have been wise to assume it anterior to proof, and to attempt to philosophize in the method thus recommended.

Again, the analogy of Astronomy has been referred to as confirming the assumption of perpetual uniformity. The analysis of the heavenly motions, it has been said supplies no trace of a beginning, no promise of an end But here, also, this analogy is erroneously applied Astronomy, as the science of cyclical motions, has nothing in common with Geology. But look at Astronomy where she has an analogy with Geology; consider our knowledge of the heavens as a palætiological science :- as the study of a past condition, from which the present is derived by causes acting in time there then no evidence of a beginning, or of a progress! What is the import of the Nebular Hypothesis? A luminous matter is condensing, solid bodies are forming. are arranging themselves into systems of cyclical motion; in short, we have exactly what we are told, on this analogy, we ought not to have ;-the beginning of a world. I will not, to justify this argument, maintain the truth of the nebular hypothesis, but if geologists wish to borrow maxims of philosophizing from astronomy, such speculations as have led to this hypothesis must be their model.

Or, let them look at any of the other provinces of palætiological speculation, at the history of states, of civilization, of languages. We may assume some resemblance or connexion between the principles which determined the progress of government, or of society. or of literature, in the earliest ages, and those which now operate; but who has speculated successfully, assuming an identity of such causes? Where do we now find a language in the process of formation, unfolding itself in inflexions, terminations, changes of vowels by grammatical relations, such as characterise the oldest known languages? Where do we see a nation, by its natural faculties, inventing writing, or the arts of life, as we find them in the most ancient civilized nations? We may assume hypothetically, that man's faculties develop themselves in these ways: but we see no such effects produced by these faculties. in our own time, and now in progress, without the

influence of foreigners.

TWO ANTAGONIST DOCTRINES OF GEOLOGY. 517

Is it not clear, in all these cases, that history does not exhibit a series of cycles, the aggregate of which may be represented as a uniform state, without indication of origin or termination? Does it not rather seem evident that, in reality, the whole course of the world, from the earliest to the present times, is but one cycle, yet unfinished;—offering, indeed, no clear evidence of the mode of its beginning; but still less entitling us to consider it as a repetition or series of

repetitions of what had gone before?

Thus we find, in the analogy of the sciences, no confirmation of the doctrine of uniformity, as it has been maintained in Geology. Yet we discern, in this analogy, no ground for resigning our hope, that future researches, both in Geology and in other palætiological sciences, may throw much additional light on the question of the uniform or catastrophic progress of things, and on the earliest history of the earth and of man. But when we see how wide and complex is the range of speculation to which our analogy has referred us, we may well be disposed to pause in our review of science;—to survey from our present position the ground that we have passed over;—and thus to collect, so far as we may, guidance and encouragement to enable us to advance in the track which lies before us.

Before we quit the subject now under consideration, we may, however, observe, that what the analogy of science really teaches us, as the most promising means of promoting this science, is the strenuous cultivation of the two subordinate sciences, Geological Knowledge of Facts, and Geological Dynamics. These are the two provinces of knowledge-corresponding to Phenomenal Astronomy, and Mathematical Mechanicswhich may lead on to the epoch of the Newton of geology We may, indeed, readily believe that we have much to do in both these departments. While so large a portion of the globe is geologically unexplored; - while all the general views which are to extend our classifications satisfactorily from one hemisphere to another, from one zone to another, are still unformed; while the organic fossils of the tropics are almost unknown, and their general relation to the existing state of things has not even been conjectured—how can we expect to speculate rightly and secure, respecting the history of the whole of our globe! In if Geological Classification and Description are thus imperfect, the knowledge of Geological Causes is all more so. As we have seen, the necessity and the method of constructing a science of such causes, we only just beginning to be perceived. Here, then a the point where the labours of geologists may be befully applied; and not in premature attempts to decide the widest and abstrusest questions which the human

mind can propose to itself.

It has been stated, 11 that when the Geological Society of London was formed, their professed object was to multiply and record observations, and patiently to await the result at some future time; and ther favourite maxim was, it is added, that the time was not yet come for a General System of Geology. This was a wise and philosophical temper, and a due appreciation of their position. And even now, their task is not yet finished, their mission is not yet accomplished. They have still much to do, in the way of collecting Facts; and in entering upon the exact estimation of Causes, they have only just thrown open the door of a vast Labyrinth, which it may employ many generations to traverse, but which they must needs explore, before they can penetrate to the Oracular Chamber of Truth.

I REJOICE, on many accounts, to find myself arriving at the termination of the task which I have attempted. One reason why I am glad to close my history is, that in it I have been compelled, especially in the latter part of my labours, to speak a. a judge respecting eminent philosophers whom I reverence as my Teachers in those very sciences on which I have had to pronounce

b Lyell, B. i. c. iv p to3.

be not too presumptuous. But I doubt not that such men are as full of candour and tolerance, as they are of knowledge and thought. And if they deem, as I did, that such a history of science ought to be attempted, they will know that it was not only the historian's privilege, but his duty, to estimate the import and amount of the advances which he had to narrate, and if they judge, as I trust they will, that the attempt has been made with full integrity of intention and no want of labour, they will look upon the inevitable imperfections of the execution of my work with in-

dulgence and hope.

There is another source of satisfaction in arriving at this point of my labours. If, after our long wandering through the region of physical science, we were left with minds unsatisfied and unraised, to ask, 'Whether this be all I'-our employment might well be deemed weary and idle If it appeared that all the vast labour and intense thought which has passed under our review had produced nothing but a barren Knowledge of the external world, or a few Arts ministering merely to our gratification, or if it seemed that the methods of arriving at truth, so successfully applied in these cases, aid us not when we come to the higher aims and prospects of our being; this History might well be estimated as no less melancholy and unprofitable than those which narrate the wars of states and the wiles of statesmen. But such, I trust, is not the impression which our survey has tended to produce. At various points, the researches which we have followed out, have offered to lead us from matter to mind, from the external to the internal world, and it was not because the thread of investigation snapped in our hands, but rather because we were resolved to confine ourselves, for the present, to the material sciences, that we did not proceed onwards to subjects of a closer interest. It will appear, also, I trust, that the most perfect method of obtaining speculative truth, -that of which I have had to relate the result,-is by no means confined to the least worthy subjects; but that the Methods of learning what is really true, though they must assume different aspects in cases where: mere contemplation of external objects is concerned, and where our own internal world of thought, feeling and will, supplies the matter of our speculations, have yet a unity and harmony throughout all the possible employments of our minds. To be able to trace such connexions as this, is the proper sequel, and would be the high reward, of the labour which has been bestowed on the present work. And if a persuasion of the reality of such connexious, and a preparation for studying them, have been conveyed to the reader's mind while he has been accompanying me through our long survey, his time may not have been employed on these pages in vain. However vague and hesitating and obscure may be such a persuasion, it belongs, I doubt not, to the dawning of a better Philosophy, which it may be my lot, perhaps, to develop more fully hereafter, if permitted by that Superior Power to whom all sound philosophy directs our thoughts.

ADDITIONS TO THE THIRD EDITION.

BOOK XI.

ELECTRICITY.

GENERAL REMARKS.

ELECTRICITY in the form in which it was originally studied—Franklinic, frictional, or statical electricity—has been so completely identified with electricity in its more comprehensive form—Voltaic, chemical, or dynamical electricity—that any additions we might have to make to the history of the earlier form of the subject are included in the later science.

There are, however, several subjects which may still be regarded rather as branches of Electricity than of the Cognate Sciences. Such are, for instance, Atmospheric Electricity, with all that belongs to Thunderstorms and Lightning Conductors. The observation of Atmospheric Electricity has been prosecuted with great zeal at various meteorological observatories; and especially at the Observatory established by the British Association at Kew. The Aurora Borealis, again, is plainly an electrical phenomenon; but probably belonging rather to dynamical than to statical electricity. For it strongly affects the magnetic needle, and its position has reference to the direction of magnetism; but it has not been observed to affect the electroscope. The general features of this phenomenon have been described by M. de Humboldt, and more recently by M. de Bravais; and theories of the mode of its production have been propounded by MM. Biot, De la Rive. Kaemtz, and others.

Again, there are several fishes which have the power of giving an electrical shock:—the torpedo, the gym-

notus, and the silurus. The agency of these creature has been identified with electricity in the most general sense. The peculiar energy of the animal has been made to produce the effects which are produced by an electrical discharge or a voltaic current — not only to destroy life in small animals, but to deflect a magnet, to make a magnet, to decompose water, and to produce a spark.

Dr. Faraday's Views of Statical Electric Induction.

According to the theories of electricity of Æpinus and Coulomb, which in this Book of our History are regarded as constituting a main part of the progress of this portion of science, the particles of the electric fluid or fluids exert forces, attractive and repulsive, upon each other in straight lines at a distance, in the same way in which, in the Newtonian theory of the universe, the particles of matter are conceived as exerting attractive forces upon each other. An electrized body presented a conducting body of any form, determines a new arrangement of the electric fluids in the conductor, attracting the like fluid to its own side, and repelling the opposite fluid to the opposite side. This is Electrical Induction. And as, by the theory, the attraction is greater at the smaller distances, the distribution of the fluid upon the conductor in virtue of this Induction will not be symmetrical, but will be governed by laws which it will require a complex and difficult calculation to determine—as we have seen was the case in the investigations of Coulomb, Poisson, and others.

Instead of this action at a distance, Dr. Faraday has been led to conceive Electrical Induction to be the result of an action taking place between the electrical body and the conductor through lines of contiguous particles in the mass of the intermediate body, which he calls the *Dielectric*. And the irregularities of the distribution of the electricity in these cases of Induction, and indeed the existence of an action in points protected from direct action by the protaberant sales

conductor, are the causes, I conceive, which lead to the conclusion that Induction takes place in dines! of such contiguous particles.

ith reference to this, I may remark that, as I have the distribution of electricity on a conductor in presence of an electrized body is so complex a rematical problem that I do not conceive any ly popular way of regarding the result can entitle say, that the distribution which we find cannot explained by the Coulombian theory, and must s us upon the assumption of an action in curved :--which is, indeed, itself a theory, and so vague a that it requires to be made much more precise re we can say what consequences it does or does lead to. Professor W. Thomson has arrived at a hematical proof that the effect of induction on the of Coulomb and of Faraday must, under certain itions, be necessarily and universally the same. lith regard to the influence of different Dielectrics 1 Induction, the inquiry appears to be of the highest rtance; and may certainly necessitate some addito the theory.

Researches, 1165, &c.

BOOK XII.

MAGNETISM.

Recent Progress of Terrestrial Magnetism.

IN Chapter II., I have noticed the history of Terrestrial Magnetism; Hansteen's map published at 1819; the discovery of 'magnetic storms' about 1825; the chain of associated magnetic observations, suggested by M de Humboldt, and promoted by the British Association and the Royal Society, the demand for the continuation of these till 1848, the magnetic observations made in several voyages; the magnetic surveys of various countries. And I have spoken also of Gauss's theory of Terrestrial Magnetism, and his directions and requirements concerning the observations to be made. I may add a few words with regard to the

more recent progress of the subject,

The magnetic observations made over large portions of the Earth's surface by various persons, and on the Ocean by British officers, have been transmitted to Woolwich. where they have been employed by General Sabinem constructing magnetic maps of the Earth for the year 1840.1 Following the course of inquiry described in the part of the history referred to, these maps exhibit the declination, inclination, and intensity of the magnetic force at every point of the earth's surface. The curves which mark equal amounts of each of these three elements (the lines of equal declination, inclination, and force:—the isogonal, the isoclinal, and the isodynamic lines,) are, in their general form, complex and irregular: and it has been made a matter of question (the facts being agreed upon) whether it be more proper to say that they indicate four poles, as Halley and as Hansteen said, or only two poles, as Gauss asserts. The matter appears

¹ These maps are published in Mr Keith Johnstone's Physical Atta-

that is, lines obtained by following the directions, or pointings, of the magnetic needle to the north or to the bouth, till we arrive at their points of convergence of all their directions, for there are only two such poles, one in the Arctic and one in the Antarctic region. But in consequence of the irregularity of the magnetic constitution of the earth, if we follow the inclination or the magnetic force round the earth on any parallel of latitude, we find that it has two maxima and two minima, as if there were four magnetic poles. The isodynamic map is a new presentation of the facts of this subject, the first having been constructed by Colonel Sabine in 1837.

I have stated also that the magnetic elements at each place are to be observed in such a manner as to bring into view both their periodical, their secular, and their irregular or occasional changes. The observations made at Toronto in Canada, and at Hobert Town in Van Diemen's Land, two stations at equal distances from the two poles of the earth, and also at St Helena, a station within the tropics, have been discussed by General Sabine with great care, and with an amount of labour approaching to that employed upon reductions of astronomical observations. And the results

have been currous and unexpected.

The declination was first examined. This magnetical element 14, as we have already seen (p. 53), hisble both to a diurnal and to an annual inequality; and also to irregular perturbations which have been termed magnetic storms. Now it was found that all these inequalities went on increasing gradually and steadily from 1843 to 1848, so as to become, at the end of that time, above twice as large as they were at the beginning of it. A new periodical change in all these elements appeared to be clearly established by this examination. M. Lamont, of Munich, had already remarked indications of a decennial period in the diurnal variation of the declination of the needle.

[·] Phil. Trans 1852 and 1856.

The duration of the period from minimum to maximum being about five years, and therefore the white period about ten years. The same conclusion was found to follow still more decidedly from the observe

tions of the dip and intensity.

This period of ten years had no familiar meaning in astronomy; and if none such had been found for it, is occurrence as a magnetic period must have been regarded, as General Sabine says,3 in the light of a fragmentary fact. But it happened about this time that the scientific world was made aware of the existence of a like period in a phenomenon which no one would have guessed to be connected with terrestrial magnetism, namely, the spots in the Sun. M Schwabe of Dessau, had observed the Sun's disk with momente perseverance for 24 years: - often examining it more than 300 days in the year; and had found that the spots had, as to their quantity and frequency, a penodical character. The years of maximum are 18:8. 1838, 1848, in which there were respectively 225,6 282, 330 groups of spots. The minimum years, 1811. This curious 1843, had only 33 and 34 such groups. fact was first made public by M. de Humboldt, in the third volume of his Kosmos (1850). The court dence of the periods and epochs of these two classes of facts was pointed out by General Sabine in a Mem r presented to the Royal Society in March, 1852.

Of course it was natural to suppose, even here this discovery, that the diurnal and annual inequality of the magnetic element at each place depend upon

the action of the sun, in some way or other.

Dr. Faraday had endeavoured to point out how the effect of the solar heat upon the atmosphere would according to the known relations of heat and magnetism, explain many of the phenomena. But this new feature of the phenomena, their quinquennial increases

The observations up to 1844 were published in Poggendeth Annales.

decrease, makes us doubt whether such an explaon can really be the true one.

the secular changes in the magnetic elements, much more is known than was known some years. These changes go on, but their laws are imperly known, and their causes not even conjectured. Hansteen, in a recent memoir, says that the case of the inclination goes on progressively dimining. With us this rate of decrease appears to be present nearly uniform. We cannot help contring that the sun, which has so plain a connexion the diurnal, annual, and occasional movements of needle, must also have some connexion with its lar movements.

a 1840 the observations made at various places to a great extent enabled Gauss, in connexion with Weber, to apply his Theory to the actual condition he Earth; and he calculated the Declination, ination, and Intensity at above 100 places, and it the agreement, as he says, far beyond his hopes, y show, he says, that the Theory comes near to Truth.

Correction of Ships' Compasses.

he magnetic needle had become of importance in it was found that it always pointed to the North, he that time the history of magnetism has had its ats reflected in the history of navigation. The age of the declination arising from a change of a terrified the companions of Columbus. The remination of the laws of this change was the cet of the voyage of Halley; and has been pursued a the utmost energy in the Arctic and Antarctic one by navigators up to the present time. Proly the dependence of the magnetic declination upon the laws have a new source of difficulty has in the ligation. But a new source of difficulty has in the

ice K. Johnstone's Physical Atlas.

tilas des Erdmagnetismus nach den Klementen der Theorie Lut.

v. See Preface.

mean time come into view; the effect of the iron methe ship upon the Compass. And this has gone on increasing as guns, cables, stays, knees, have been made of iron: then steam engines with funnels, wheels, and screws, have been added; and finally the whole ship has been made of iron. How can the compass be trusted in such cases?

In la star Line

I have already said in the history that Mr. Barlow proposed to correct the error of the compass by placing near to the compass an iron plate, which from its profinity to the compass might counterbalance magnetically the whole effect of the ship's iron upon the compass. This correction was not effectual, because the magnetic forces of the plate and of the ship do not change their direction and value according to the same law, with the change of position. I have further stated that Mr. Airy devised other means of correcting the error I may add a few words on the subject, for the subject has been further examined by Mr. Airy and by others

It appears, by mathematical reasoning, that the magnetic effect of the iron in a ship may be regarded as producing two kinds of deviation which are added together; - a 'polar-magnet deviation,' which change from positive to negative as the direction of the ships keel, in a horizontal revolution, passes from semiciror to semicircle, and a 'quadrantal deviation,' which changes from positive to negative as the keel turus from quadrant to quadrant. The latter deviation may be remedied completely by a mass of unmagnetized iros placed on a level with the compass, either in the athwartship line or in the fore and aft line, according to circumstances. 'The polar-magnet deviation' may be corrected at any given place by a magnet or magnets, but the magnets thus applied at one place will not always correct the deviation in another magnetic lautude. For it appears that this deviation arises partly from a magnetism inherent in the materials of the ship, not changing with the change of magnetic post tion, and partly from the effect of terrestrial magne-

⁵ Phil Truns, 1856.

tism upon the ship's iron. But the errors arising from both sources may be remedied by adjusting, at a new locality, the positions of the corrective magnets.

The inherent magnetism of the ship, of which I have spoken, may be much affected by the position in which the ship was built; and may change from time to time; for instance, by the effect of the battering of the waves, and other causes. Hence it is called by

Mr. Airy 'sub permanent magnetism.'

Another method of correcting the errors of a ship's compass has been proposed, and is used to some extent; namely, by sminging the ship round (in harbour) to all points of azimuth, and thus constructing a Table of Compass Errors for that particular ship. But to this method it is objected that the Table loses its value in a new magnetic latitude much more than the correction by magnets does; besides the inconveniences of steering a ship by a Table.

BOOK XIII.

VOLTAIC ELECTRICITY.

CHAPTER VIII.

MAGNETO-ELECTRIC INDUCTION.

FARADAY'S discovery that, in combinations like those in which a voltaic current was known to produce motion, motion would produce a voltaic current, naturally excited great attention among the scientific men of Europe. The general nature of his discovery was communicated by letter 1 to M. Hachette at Paris, in December, 1831; and experiments having the like results were forthwith made by MM. Becquerel and Ampère at Paris, and MM. Nobili and Antinori at Florence.

It was natural also that in a case in which the relations of space which determine the results are so complicated, different philosophers should look at them in different ways. There had been, from the first decovery by Oersted of the effect of a voltaic current upon a magnet, two rival methods of regarding the facts. Electric and magnetic lines exert an effort w place themselves transverse to each other (see chapter iv. of this Book), and (as I have already said) two wars offered themselves of simplifying this general truth to suppose an electric current made up of transverse magnetic lines; or to suppose magnetic lines made up of transverse electric currents. On either of these assumptions, the result was expressed by saving that like currents or lines (electric or magnetic) tend to place themselves parallel; which is a law more generally intelligible than the law of transverse position Faraday had adopted the former view; had taken the lines of magnetic force for the fundamental lines of las system, and defined the direction of the magneto-electric

Ann. de Chimie, vol z'vill. (1811), p. 402

current of induction by the relation of the motion to these lines. Ampère, on the other hand, supposed the magnet to be made up of transverse electric currents (chap. vi.); and had deduced all the facts of electrodynamical action, with great felicity, from this conception. The question naturally arose, in what manner, on this view, were the new facts of magneto electric induction by motion to be explained, or even expressed?

Various philosophers attempted to answer this question. Perhaps the form in which the answer has obtained most general acceptance is that in which it was put by Lenz, who discoursed on the subject to the Academy of St. Petersburg in 1833.2 His general rule is to this effect: when a wire moves in the neighbourhood of an electric current or a magnet, a current takes place in it, such as, existing independently, would have produced a motion opposite to the actual motion. Thus two parallel forward currents move towards each other: -hence if a current move towards a parallel wire, it produces in it a backward current. A moveable wire conducting a current downwards will move round the north pole of a magnet in the direction N., W., S., E.: -hence if, when the wire have in it no current, we move it in the direction N., W., S., E., we produce in the wire an upward current. And thus, as M. de la Rive remarks,3 in cases in which the mutual action of two currents produces a limited motion, as attraction or repulsion, or a deviation right or left, the correaponding magneto-electric induction produces an inst intaneous current only; but when the electrodynamic action produces a continued motion, the corresponding motion produces, by induction, a continued current.

Looking at this mode of stating the law, it is impossible not to regard this effect as a sort of reaction; and accordingly, this view was at once taken of it. Professor Ritchie said, in 1833, 'The law is founded on the universal principle that action and reaction are equal.' Thus, if voltaic electricity induce magnetism

Acad. Petrop. Nov. 29, 1833. Pogg. Ann. vol. xxxi. p. 483.
 Traite de l Electricité, vol. i. p. 441 (1854).

under certain arrangements, magnetism will, by similar arrangements, react on a conductor and induce voltage

electricity.4

There are still other ways of looking at this matter, I have elsewhere pointed out that where polar properties co-exist, they are generally found to be connected,5 and have illustrated this law in the case of electrical, magnetical, and chemical polarities If we regard motion backwards and forwards, to the right and the left, and the like as polar relations, we see that magneto-electric induction gives us a new manifestation of connected polarities.

Diamagnetic Polarity.

But the manifestation of co existent polarities which are brought into view in this most curious department of nature is not yet exhausted by those which we have described. I have already spoken (chap av.) of In. Faraday's discovery that there are diamagnetic as well as magnetic bodies; bodies which are repelled by the pole of a magnet, as well as bodies which are attracted Here is a new opposition of properties. What is the exact definition of this opposition in connexion with other polarities? To this, at present, different philosophers give different answers. Some say that diamagnetism is completely the opposite of ordinary magnetism, or, as Dr Faraday has termed it for the sake of distinction, of paramagnetism. They say that as the north pole of a magnet gives to the neighbouring extremity of a piece of soft iron a south pole, so it gives to the neighbouring extremity of a piece of bismuth a north por and that the bismuth becomes for the time an inverted magnet; and hence, arranges itself across the line of magnetised force, instead of along it. Dr. Faraday

⁶ On the Reduction of Mr. In the second edition of the Faraday's discoveries in Magneto- history I used the like expreelectric Induction to a General sions. Law Trans. of R. S to Phil Mag. NS vol. iii 37, and vol. iv p ii.

⁺ Phil Ind. Sc B. v. e fi.

himself at first adopted this view; but he now conceives that the bismuth is not made polar, but is simply repelled by the magnet, and that the transverse position which it assumes, arises merely from its elongated form, each end trying to recede as far as possible from the

repulsive pole of the magnet.

Several philosophers of great eminence, however, who have examined the subject with great care, adhere to Dr. Faraday's first view of the nature of Diamagnetism—as W. Weber, Plucker, and Mr. Tyndall among ourselves. If we translate this view into the language of Ampère's theory, it comes to this:—that as currents are induced in iron and magnetics parallel to those existing in the inducing magnet or battery wire; so in bismuth, heavy glass, and other diamagnetic bodies, the currents induced are in the contrary directions:—these hypothetical currents being in non-conducting diamagnetic, as in magnetic bodies, not in the mass, but round the particles of the matter.

Magneto optic Effects and Magnecrystallic Polarity.

Not even yet have we terminated the enumeration of the co-existent polarities which in this province of nature have been brought into view. Light has polar properties; the very term polarization is the record of the discovery of these. The forces which determine the crystalline forms of bodies are of a polar nature: crystalline forms, when complete, may be defined as those forms which have a certain degree of symmetry in reference to opposite poles. Now has this optical and crystalline polarity any relation to the electrical polarity of which we have been speaking?

However much we might be disposed beforehand to conjecture that there is some relation between these two groups of polar properties, yet in this as in the other parts of this history of discoveries respecting polarities, no conjecture hits the nature of the relation, such as experiment showed it to be. In November,

Faraday's Researches, Art. 2429, 2410.
7 Paggendorf's Ann. Jou. 1848.

1846, Faraday announced the discovery of what he then called 'the action of magnets on light.' But the action was manifested, not on light directly, but on light passing through certain kinds of glass. When this glass, subjected to the action of the powerful magnets which he used, transmitted a ray of light parallel to the line of magnetic force, an effect was produced upon the light. But of what nature was this effect? When light was ordinary light, no change in its condition was discoverable. But if the light were light polarized in any plane, the plane of polarization was turned round through a certain angle while the ray passed through the glass.—a greater angle, in proportion as the magnetic force was greater, and the thickness of the glass greater.

A power in some respects of this kind, namely, a power to rotate the plane of polarization of a ray passing through them, is possessed by some bodies in their natural state; for instance, quartz crystals, and oil of turpentine. But yet, as Dr. Faraday remarks, there is a great difference in the two cases. When polarized rays pass through oil of turpentine, in whatever direction they pass, they all of them have their plane of polarization rotated in the same direction; that is, all to the right or all to the left; but when a ray passes through the heavy glass, the power of rotation exists only in a plane perpendicular to the magnetic line, and its direction as right or left-handed in

reversed by reversing the magnetic polarity.

In this case, we have optical properties, which do not depend on crystalline form, affected by the magnetic force. But it has also been found that crystalline form, which is so fertile a source of optical properties, affords indications of magnetic forces. In 1847, M. Plucker, 10 of the University of Bonn, using a powerful magnetic apparatus, similar to Faraday's, found that crystals in general are magnetic, in this

Billouted borate of lead. See Researches, § 2151, &c. Also flat glass, rock sait, water (2215).

Rescurches, Art. 2231 " Taylor's Scientific Memoirs, vol. 3

sense, that the axes of crystalline form tend to assume a certain position with reference to the magnetic lines of force. The possession of one optic axis or of two is one of the broad distinctions of the different crystalline forms: and using this distinction, M. Plücker found that a crystal having a single optic axis tends to place itself with this axis transverse to the magnetic line of force, as if its optic axis were repelled by each magnetic pole; and crystals with two axes act as if each of these axes were repelled by the magnetic poles. This force is independent of the magnetic or diamagnetic character of the crystal; and is a directive, more properly than an attractive or repulsive force.

Soon afterwards (in 1848) Faraday also discovered 11 an effect of magnetism depending on crystalline form, which at first sight appeared to be different from the effects observed by M. Plucker. He found that a crystal of bismuth, of which the form is nearly a cube, but more truly a rhombohedron with one diagonal a little longer than the others, tends to place itself with this diagonal in the direction of the lines of magnetic force. At first he conceived 12 the properties thus detected to be different from those observed by M. Plucker; since in this case the force of a crystalline axis is axial, whereas in those, it was equatorial. But a further consideration of the subject, led him13 to a conviction that these forces must be fundamentally identical for it was easy to conceive a combination of bismuth crystals which would behave in the magnetic field as a crystal of calcapar does, or a combination of calcspar crystals which would behave as a crystal of bismuth does.

And thus we have fresh examples to show that the Connexion of co-existent Polarities is a thought deeply seated in the minds of the profoundest and most sagacious philosophers, and perpetually verified and illustrated, by unforeseen discoveries in unguessed forms, through the labours of the most skilful experimenters.

¹¹ Researches, Art. 2454, &c. 12 Art. 1469. 13 Art. 2593, 2601.

Magneto-electric Machines.

The discovery that a voltaic wire moved in presence of a magnet, has a current generated in it, was cuployed as the ground of the construction of mach as to produce electrical effects. In Saxton's muchine two coils of wire including a core of soft iron revolved opposite to the ends of a horseshoe magnet, and thus, as the two coils came opposite to the N. and & and to the S. and N poles of the magnet, currents were generated alternately in the wires in opposite directions. But by arranging the counexions of the ends of the wires, the successive currents might be made to pass in corresponding directions. The alternations or anccessions of currents in such machines are governed by a contrivance which alternately interrupts and permits the action, this contrivance has been caded a rheotome. Clarke gave a new form to a machine of the same nature as Saxton's. But the like effect may be produced by using an electro-magnet instead of a common magnet. When this is done, a current is produced which by induction produces a current in another wire, and the action is alternately excited and interrupted. When the inducing current is interrupted, a momentary current in an opposit direction is produced in the induced wire; and when this current stops, it produces in the inducing wire a current in the original direction, which may be adjusted so as to reinforce the resumed action of the original current. This was pointed out by M. De la Rive in 1843.16 Machines have been constructed on such principles by him and others. Of such machines the most powerful hitherto known is that constructed by M Ruhmkorff. The effects of this instrument are exceedingly energetic.

Applications of Electrodynamic Discoveries.

The great series of discoveries of which I have bud to speak have been applied in many important ways

to the uses of life. The Electric Telegraph is one of the most remarkable of these. By wires extended to the most distant places, the electric current is transmitted thither in an imperceptible time, and by means of well devised systems of operation, is made to convey from man to man words, which are now most emphatically 'winged words.' In the most civilized states such wires now form a net-work across the land, which is familiar to our thoughts as the highway is to our feet; and wide seas have such pathways of human thought buried deep in their waves from shore to shore. Again, by using the chemical effects of electrodynamic action, of which we shall have to speak in the next Book, a new means has been obtained of copying, with an exactness unattainable before, any forms which art or nature has produced, and of covering them with a surface of metal. The Electrotype Process is now one of the great powers which manufacturing art employs.

But these discoveries have also been employed in explaining natural phenomena, the causes of which had before been altogether inscrutable. This is the case with regard to the diurnal variation of the magnetic needle; a fact which as to its existence is universal in all places, and which yet is so curiously diverse in its course at different places. Dr Faraday has shown that some of the most remarkable of these diversities, and probably all, seem to be accounted for by the different magnetic effects of air at different temperatures: although, as I have already said, (Book xii.) the discovery of a decennial period in the diurnal changes of magnetic declination shows that any explanation of those changes which refers them to causes existing in the atmosphere must be very

incomplete.15

BOOK XIV.

CHEMISTRY.

CHAPTER IX.

THE ELECTRO-CHEMICAL THEORY.

A MONG the consequences of the Electro-chemical Theory, must be ranged the various improvements which have been made in the voltaic battery. Daniel introduced between the two metals a partition permeable by chemical action, but such as to allow of two different acid solutions being in contact with the two metals. Mr. Grove's battery, in which the partition is of porous porcelain, and the metals are platinum and amalgamated zinc, is one of the most powerful hitherto known. Another has been constructed by Dr. Callan, in which the negative or conducting plate is a cylinder of cast iron, and the positive element a cylinder of amalgamated zinc placed in a porous cell. This also has great energy.

The Number of Elementary Substances.

There have not been, I believe, any well-established additions to the list of the simple substances recognized by chemists. Indeed the tendency at present appears to be rather to deny the separate elementary character of some already announced as such substances. Pelopium and Niobium were, as I have said, two of the new metals. But Naumann, in his Elemente der Mineralogie (4th ed. 1855), says, in a foot note (page 25): 'Pelopium is happily again got rid of, for Pelopic Acid and Niobic Acid possess the same Radical. Donarium had a still shorter existence.'

In the same way, when Hermann imagined that he

had discovered a new simple metallic substance in the mineral Samarskite from Miask, the discovery was disproved by H. Rose (*Pogg. Ann. B.* 73, 8, 449).

In general the insulation of the new simple substances, the metallic bases of the earths, and the like,—their separation from their combinations, and the exhibition of them in a metallic form—has been a difficult chemical process, and has rarely been executed on any considerable scale. But in the case of Aluminium, the basis of the earth Alumina, the process of its extraction has recently been so much facilitated, that the metal can be produced in abundance. This being the case, it will probably soon be applied to special economical uses, for which it is fitted by possessing special properties.

BOOK XV.

MINERALOGY.

DY the kindness of W. H. Miller, Esq., Professor of Mineralogy in the University of Cambridge, I am able to add to this part the following notices of books and memoirs.

Crystallography,

Elemente der Krystallographie, nebst einer tabellarischen Uebersicht der Mineralien nach der Krystallformen, von Gustav Rose. 2. Auflage Berlin, 1838. The crystallographic method here adopted is, for the most part, that of Weiss. The method of this work has been followed in

A System of Crystallography, with its Applications to Mineralogy, By John Joseph Griffin. Glasgow, 1841. Mr. Griffin has, however, modified the notation of Rose. He has constructed a series of models of crystalline forms.

Frankenheim's System der Krystalle. 1842. work adopts nearly the Mohsian systems of crystallization. It contains Tables of the chemical constitution, inclinations of the axes, and magnitude of the axes of all the crystals of which a description was to be found, including those formed in the laboratory, as well as those usually called minerals; 713 in all.

Fr. Aug. Quenstedt, Methode der Krystallographis, 1840, employs a fanciful method of representing a crystal by projecting upon one face of the crystal all the other faces. This invention appears to be more

curious than useful.

Dr. Karl Naumann, who is spoken of in Chap. IL. of this Book, as the author of the best of the Mixed Systems of Classification, published also Grundrin der Krystallographie. Leipzig, 1826. In this and ther works he modifies the notation of Mohs in a

very advantageous manner.

Professor Dana, in his System of Mineralogy, New Laven (U.S.), 1837, follows Naumann for the most art, both in crystallography and in mineral classification. In the latter part of the subject, he has made he attempt, which in all cases is a source of confusion and of failure, to introduce a whole system of new ames of the members of his classification.

The geometry of crystallography has been investipted in a very original manner by M. Bravais, in impers published in the Journal of the Ecole Polytechtique, entitled Mémoires sur les Systèmes formés par les Points. 1850. Etudes Crystallographiques. 1851.

Hermann Kopp (Einleitung in die Krystallographie, Braunschweig, 1849) has given the description and peasurement of the angles of a large number of labo-

story crystals.

Rammelsberg (Krystallographische Chemie, Berlin, 1855) has collected an account of the systems, simple brins and angles of all the laboratory crystals of which

ne could obtain descriptions.

Schabus of Vienna (Bestimmung der Krystallgestalten in Chemischen Laboratorien erzeugten Producte, Wien, 1855; a successful Prize Essay) has given a lescription, accompanied by measurements, of 90 crys-

alline species from his own observations.

implify and improve crystallography, I may add a remarkable Essay very recently made here by Mr. Brooke, and suggested to him by his exact and familiar knowledge of Mineralogy. It is to this effect. All the crystalline forms of any given mineral species are derived from the primitive form of that species, and the degree of symmetry, and the parameters, of this form determine the angles of all derivative forms. But how is this primitive form selected and its parameters determined! The selection of the kind of the primitive form depends upon the degree of symmetry which appears in all the derivative forms; according to worth they belong to the rhombohedral, prismatic, square

pyramidal, or some other system: and this determination is commonly clear. But the parameters, or the angles. of the primitive form, are commonly determined by the cleavage of the mineral. Is this a sufficient and necessary ground of such determination? May not a simplification be effected, in some cases, by taking some other parameters? by taking a primitive form which belongs to the proper system, but which has some other angles than those given by cleavage? Brooke has tried whether, for instance, crystals of the rhombohedral system may not be referred with advantage to primitive rhombohedrons which have, in all the species, nearly the same angles. The advantage to be obtained by such a change would be the simplification of the laws of derivation in the derivative forms: and therefore we have to ask, whether the indices of derivation are smaller numbers in this way or with the hitherto accepted fundamental angles. It appears to me, from the examples given, that the advantage of simplicity in the indices is on the side of the old system: but whether this be so or not, it was a great benefit to crystallography to have the two methods compared. Mr. Brooke's Essay is a Memoir presented to the Royal Society in 1856.

2. Optical Properties of Minerals.

The Handbuch der Optik, von F. W. G. Radicke, Berlin, 1839, contains a chapter on the optical properties of crystals. The author's chief authority is Sir D. Brewster, as might be expected.

M. Haidinger has devoted much attention to experiments on the *pleochroism* of minerals. He has invented an instrument which makes the dichroism or minerals more evident by exhibiting the two colours

aide by aide.

The pleochroism of minerals, and especially the remarkable clouds that in the cases of Iolite, Andalusite, Augite, Epidote, and Aximte, border the positions of either optical axis, have been most successfully indicated.

I. de Senarmont by means of artificial orystalliza-

. (Ann. de Chim. 3 Ser. xli. p. 319.)

L Pasteur has found that Racemic Acid consists of different acids, having the same density and comtion. The salts of these acids, with bases of Amia and of Potassa, are hemihedral, the hemihedral which occur in the one being wanting in the r. The acids of these different crystals have cirrolarization of opposite kinds. (Ann. de Chim. r. xxviii. 56, 99.) This discovery was marked by assignation of the Rumford Medal to M. Pasteur 856.

I. Marbach has discovered that crystals of chlorate oda, which apparently belongs to the cubic or test system, exhibit hemihedral faces of a peculiar acter; and that the crystals have circular polarizate of opposite kinds in accordance with the differences plagihedral faces. (Poggendorf's Annalen, xci.

Seydolt of Vienna has found a means of detectplagihedral faces in quartz crystals which do not al them externally. (Akad. d. Wissenschoft zu a, B. xv. s. 59.)

3. Classification of Minerals.

the Philosophy of the Inductive Sciences, B. VIII.

i., I have treated of the Application of the Natural
my Method of Classification to Mineralogy, and

apoken of the Systems of this kind which have

proposed. I have there especially discussed the

m proposed in the treatise of M. Necker, Le Règne

eral ramené aux Méthodes d'Histoire Naturelle

is, 1835). More recently have been published M.

dant's Cours élémentaire d'Histoire Naturelle Minérie (Paris, 1841); and M. A. Dufresnoy's Traité

linéralogie (Paris, 1845). Both these works are

ar governed by mere chemical views that they

into the inconveniences and defects which are

ied in the best systems of German mineralogists,

to last mineral system of Berzehus has been de-

veloped by M. Rammelsberg (Nürnberg, 1847). It s in principle such as we have described it in the bisters.

M. Nordenskiold's system (3rd Ed 1840.) has been criticised by G Rose, who observes that it removes the defects of the system of Berzelius only in part. He himself proposes what he calls a 'Krystallo-Chenasches System,' in which the crystalline form determines the genus and the chemical composition the species. His classes are—

1. Simple Substances.

2. Combinations of Sulphur, Selenium, Titanium, Arsenic, Antimony.

3. Chlorides, Fluorides, Bromides, Iodides.

4. Combinations with Oxygen.

We have already said that for us, all chemical compounds are minerals, in so far that they are included in our classifications. The propriety of this mode of dealing with the subject is confirmed by our finding that there is really no tenable distinction between native minerals and the products of the laborators. A great number of emineut chemists have been employed in producing, by artificial means, crystals which had before been known only as native products.

BOOK XVI.

CLASSIFICATORY SCIENCES.

BOTANY.

POR the purpose of giving to my reader some indication of the present tendency of Botanical Science, I conceive that I cannot do better than direct his attention to the reflexions, procedure, and reasonings which have been suggested by the most recent extensions of man's knowledge of the vegetable world. And as a specimen of these, I may take the labours of Dr. Joseph Hooker, on the Flora of the Antarctic Regions, 1 and especially of New Zealand. Dr. Hooker was the Botanist to an expedition, commanded by Sir James Ross, sent out mainly for the purpose of investigating the phenomena of Terrestrial Magnetism near the South Pole, but directed also to the improvement of Natural History. The extension of botanical descriptions and classifications to a large mass of new objects necessarily suggests wider views of the value of classes (genera, species, &c.), and the conclusions to be drawn from their constancy or inconstancy. A few of Dr. Hooker's remarks may show the nature of the views taken under such circumstances.

I may notice, in the first place, (since this work is intended for general rather than for scientific readers,) Dr. Hooker's testimony to the value of a technical descriptive language for a classificatory science—a Terminology, as it is called. He says, 'It is impossible to write Botanical descriptions which a person ignorant of Botany can understand, although it is supposed by

¹ The Botany of the Antarctic Voyage of H M Discovery Ships Erebus and Terror, in the years 1839-1840. Published 1847. Flora Accas Scienciae 1853.

many unacquainted with science, that this can and should be done.' And hence, he says, the state of botanical science demands Latin descriptions of the plants; and this is a lesson which he especially urges upon the Colonists who study the indigenous plants.

Dr. Hooker's remarks on the limits of species, their dispersion and variation, are striking and instructive He is of opinion that species vary more, and are more widely diffused, than is usually supposed. Hence be conceives that the number of species has been needlessy and erroneously multiplied, by distinguishing the specimens which occur in different places, and vary in unessential features. He says that though, according to the lowest estimate of compilers, 100,000 is the commonly received number of known plants, he thinks that half that number is much nearer the truth. 'The,' he says, 'may be well conceived, when it is notonous that nineteen species have been made of the Common Potato, and many more of Solanum nigrum alone Pteris aquilina has given rise to numerous book species; Vernonia cinerea of India to fifteen at least. . Many more plants are common to most countries than is supposed; I have found 60 New Zealand flowering plants and o Ferns to be European ones, besides inhabiting numerous intermediate countries. . . . So long ago as 1814, Mr. Brown drew attention to the importance of such considerations, and gave a list of 150 European plants common to Australia.

As an example of the extent to which unessential differences may go, he says (p. xvii.), 'The few remaining native Cedars of Lebanon may be abnormal states of the tree which was once spread over the whole of the Lebanon; for there are now growing in England varieties of it which have no existence in a wild state. Some of them closely resemble the Cedars of Atlas and of the Himalayas (Deodar); and the absence of any valid botanical differences tends to prove that all, though generally supposed to be different species, are

one.'

Still the great majority of the species of plants in those Southern regions are peculiar. 'There are

upwards of 100 genera, subgenera, or other well-marked groups of plants, entirely or nearly confined to New Zealand, Australia, and extra-tropical South America. They are represented by one or more species in two or more of those countries, and thus effect a botanical relationship or affinity between them all which every botanist appreciates.'

In reference to the History of Botany, I have received corrections and remarks from Dr. Hooker, with

which I am allowed to enrich my pages.

P. 220 Note 3. Nelumbrum speciesum, the Lotus of India. The Nelumbrum does not float, but raises both leaf and flower several feet above the water: the Nymphæa Lotus has floating leaves. Both enter largely into the symbolism of the Hindoos, and are often confounded.

'P. 225. Note 5. For Arachnis read Arachis. The Arachidan of Theophrastus cannot, however, be the Arachis or ground nut.

Pp. 257 and 264. For Harlecamp read Hartecamp,

P. 349. For Karlen rend Kalm.
P. 349. For Asbech rend Osbeck.

'P. 253. John Ray. Ray was further the author of the present Natural System in its most comprehensive sense. He first divided plants into Flowerless and Flowering; and the latter into Monocotyledonous and Dicotyledonous — Floriferas dividemus in Dicotyletones, quarum semina sata binis folus, seminalibus dictis, que cotyledonorum usum præstant, e terra exeunt, vel in binos saltem lobos dividuntur, quamvis eos supra terram foliorum specie non efferant, et Monocotyledones, que nec folia bina seminalia efferunt nec lobos binos condunt. Hec divisio ad arbores etiam extendi potest; siquidem Palme et congeneres hoc respectu eodem modo a reliquis arboribus different quo Monocotyledones a reliquis herbis.'

P. 282. Endogenous and Exogenous Growth. The exact course of the wood fibres which traverse the stems of both Monocotyledonous and Dicotyledonous plants has been only lately discovered. In the Monocotyledons, those fibres are collected in bundles, which follow

a very peculiar course:—from the base of each leaf th v may be followed downwards and inwards, towards : " axis of the trunk, when they form an arch with the convexity to the centre, and curving outwards again, reach the circumference, where they are lost amongst the previously deposited fibres. The intrusion of the bases of these bundles amongst those already deposites, causes the circumference of the stem to be harder than the centre, and as all these arcs have a short course (their chords being nearly equal), the truck does not increase in girth, and grows at the apex only The wood-bundles are here definite. In the Incotvledonous trunks, the layers of wood run in paratel courses from the base to the top of the trunk, exca externally to that last formed, and the trunk increases both in height and girth; the wood bundles are here indefinite.

'With regard to the Cotyledons, though it is often difficult to distinguish a Monocotyledonous Embryo from a Dicotyledonous, they may always be discriminated when germmating. The Cotyledors when two or more, and primordial leaves (when no Cotyledons are visible) of a Monocotyledon, are alter-

nate, those of a Dicotyledon are opposite.

'A further physiological distinction between Mono-cotyledons and Dicotyledons is observed in germination, when the Dicotyledonous radicle clongates and forms the root of the young plant; the Monocotyledonous radicle does not clongate, but pushes out rootlets from itself at once. Hence the not very good terms, exertized for Dicotyledonous, and endorhizal for Monocotyledonous.

The highest physiological generalization in the vege-table kingdom is between Pharnogama and Cryptogama. In the former, fertilization is effected by a pollen tube touching the nucleus of an ovule; in Cryptogams, the same process is effected by the contact of a sperm-cell, usually ciliated (antherozoud), upon another kind of cell called a germ-cell. In Pharnogams, turther, the organs of fructification are all modified leaves, those of Cryptogams are not homologous? (J. D. H.)

ZOOLOGY.

I have exemplified the considerations which govern cological classification by quoting the reflexions which Curier gives us, as having led him to his own classification of Fishes. Since the varieties of Quadrupeds, or Mammals (omitting whales, &c.), are more familiar to the common reader than those of Fishes, I may notice some of the steps in their classification; the more so as some curious questions have recently arisen thereupon.

Linnaus first divides Mammals into two groups, as they have Claws, or Hoofs (unguiculata, ungulata.) But he then again divides them into six orders (omitting whales, &c), according to their number of incisor,

laniary, and molar teeth; namely:-

Primates. (Man, Monkey, &c.)
Bruta. (Rhinoceros, Elephant, &c.)
Feræ. (Dog, Cat, Bear, Mole, &c.)
Glires. (Monse, Squirrel, Hare, &c.)

Pecora. (Camel, Graffe, Stag, Goat, Sheep, Ox, &c.)
Belluce. (Horse, Hippopotamus, Tapir, Sow, &c.)

In the place of these, Cuvier, as I have stated in the Philosophy (On the Language of Sciences, Aphorism xvi.), introduced the following orders: Bimanes, Quadrum ines, Carnasners, Rongeurs, Edentés, Pachyderms, Ruminans. Of these, the Carnassiers correspond to the Ferze of Linneus; the Rongeurs to his Glires; the Edentés are a new order, taking the Sloths, Ant-esters, &c., from the Bruta of Linneus, the Megatherium from extinct animals, and the Ornithorhynchus, &c, from the new animals of Australia; the Ruminans agree with the Pecora; the Pachyderms include some of the Bruta and the Belluce, comprehending also extinct animals, as Anoplotherium and Palæotherium.

But the two orders of Hoofed Animals, the Pachyderms and the Ruminants, form a group which is held by Mr. Owen to admit of a better separation, on the ground of a character already pointed out by Cuvier; namely, as to whether they are two-toed or three toed.

According to this view, the Horse is connected with

the Tapir, the Palmotherium, and the Rhinoceros pel only by his teeth, but by his feet, for he has really three And Cuvier notices that in the two tord or even-tood Pachyderms, the astragalus bone has its fact divided into two equal parts by a ridge, while in the uneven-tood pachy derms it has a narrow cuboid face. Mr. Owen has adopted this division of Pachyderms and Ruminants, giving the names artiodactyla and person dactyla to the two groups; the former including the Ox, Hog, Peccary, Hippopotamus, &c., the latter comprehending the Horse, Tapir, Rhinoceros, Hyrax, And thus the Ruminants take their place as a subordinate group of the great natural even-tood Division of the Hoofed Section of Mammals; and the Horse is widely separated from them, inasmuch as he belongs to the odd-toed division.2

As we have seen, these modern classifications are so constructed as to include extinct as well as long species of animals; and indeed the species which have been discovered in a fossil state have tended to fill up the gaps in the series of zoological forms which had marred the systems of modern zoologists. This has been the case with the division of which we are speaking

Mr Owen had established two genera of extract Herbivorous Animals, on the strength of fossil remains brought from South America — Toxodom, and Acodom. In a recent communication to the Royal Society he has considered the bearing of these genera upon the divisions of odd-toed and even-toed animals. He had already been led to the opinion that the three sections, Proboscidea, Perissodactyla, and Artiodactyla, formed a natural division of Ungulata; and he is now led to think that this division implies another group, 'a datinet division of the Ungulata, of equal value, if not with the Perissodactyla and Artiodactyla, at least with the Proboscidea.' This group he proposes to call Toxodonta.

Owen, Odontography.

BOOK XVII.

PHYSIOLOGY AND COMPARATIVE ANATOMY.

VEGETABLE MORPHOLOGY.

P. 481.—Morphology in Linnaus.

HAVE stated that Linnaus had some views on this subject. Dr. Hooker conceives these views to be more complete and correct than is generally allowed, though unhappily clothed in metaphorical language and mixed with speculative matter. By his permission I insert some remarks which I have received from him.

The fundamental passage on this subject is in the Systema Nature; in the Introduction to which work

the following passage occurs:-

'Prolepsis (Anticipation) exhibits the mystery of the metamorphosis of plants, by which the herb, which is the larva or imperfect condition, is changed into the declared fructification: for the plant is capable of producing either a leafy herb or a fructification

'When a tree produces a flower, nature anticipates the produce of five years where these come out all at once; forming of the bud leaves of the next year bracts; of those of the following year, the calyx; of the following, the corolla, of the next, the stamma; of the subsequent, the pistule, filled with the granulated marrow of the seed, the terminus of the life of a vegetable.'

Dr. Hooker says, 'I derive my idea of his having a better knowledge of the subject than most Botanists admit, not only from the *Prolepsis*, but from his paper called *Reformatio Botanices* (Amæn. Acad. vol. vi); a remarkable work, in respect of his candour in speaking of his predecessors' labours, and the sagacity he shows in indicating researches to be undertaken or completed.

axil of the lead axil of the lead axil of the lead tions and experimental declarations are declarations. The property calyx, corolla, metamorphosed AMPLES, both from sented by those

was that relating into two leaves. into two leaves. says it was a puze consulted Fries that such monst hood, and procuminute and mash shows no little sk of the whole matt of all their flora stamens, of which ibus me non in coloco folia pistillacer frequentissima.' I

guage more obscure, much might be inferred from the wide range and accuracy of the observations he details so scientifically. It is inconceivable that a man should have traced the sequence of the phenomena under so many varied aspects, and shown such skill, knowledge, ingenuity, and accuracy in his methods of observing and describing, and yet missed the rationale of the whole. Eliminate the speculative parts, and there is not a single error of observation or judgment; whilst his history of the developement of buds, leaves, and floral organs, and of various other obscure matters of equal interest and importance, are of a very high order of merit, are, in fact, for the time, profound.

'There is nothing in all this that detracts from the merit of Goethe's re-discovery. With Goethe it was, I think, a deductive process,—with Linnæus an inductive. Analyse Linnæus's observations and method, and I think it will prove a good example of inductive

reasoning.

'P. 441. Perhaps Professor Auguste St. Hilaire of Montpellier should share with De Candolle the honour of contributing largely to establish the metamorphic doctrine;—their labours were cotemporaneous.

'P. 442. Linnaus pointed out that the pappus was calyx: 'Et pappum gigni ex quarti anni folis, in jam nominatis Carduis.'—Prol. Plant. 338.' (J. D. H.)

CHAPTER VII,

ANIMAL MORPHOLOGY.

THE subject of Animal Morphology has recently been expanded into a form strikingly comprehensive and systematic by Mr. Owen; and supplied by him with a copious and carefully-chosen language; which in his hands facilitates vastly the comparison and appreciation of the previous labours of physiologists, and opens the way to new truths and philosophical generalizations. Though the steps which have

I will borrow my view of them mainly from him, with the less scruple, inasmuch as he has brought into

full view the labours of his predecessors.

I have stated in the History that the skeletons of all vertebrate animals are conceived to be reducible to a single Type, and the skull reducible to a series of vertebræ. But masmuch as this reduction includes not only a detailed correspondence of the bones of man with those of beasts, but also with those of birds, fishes, and reptiles, it may easily be conceived that the similarities and connexions are of a various and often remote kind. The views of such relations, held by previous Comparative Anatomists, have led to the designations of the bones of animals which have been employed in anatomical descriptions, and these designations having been framed and adopted by anatomists looking at the subject from different sides, and having different views of analogies and relations, have been very various and unstable, besides being often of cumbrous length and inconvenient form.

The corresponding parts in different animals are called homologues, a term first applied to anatomy by the philosophers of Germany, and this term Mr. Owen adopts, to the exclusion of terms more loosely denoting identity or similarity. And the Homology of the various bones of vertebrates having been in a grest degree determined by the labours of previous anatomusts, Mr. Owen has proposed names for each of the bones: the condition of such names being, that the homologues in all vertebrates shall be called by the same name, and that these names shall be founded upon the terms and phrases in which the great anatomists of the 16th, 17th, and 18th centuries expressed the results of their researches respecting the human skeleton. These names, thus selected, so far as concerned the bones of the Head of Fishes, one of the most difficult cases of this Special Homology, he published in a Table, in which they

¹ Lectures on Vertebrates 1846, p. 158. And On the Archetype and Homologies of the Vertebrate Skeleton. 1848, p. 172.

were compared, in parallel columns, with the names or phrases used for the like purpose by Cuvier, Agassiz, Geoffroy, Hallman, Sæmmering, Meckel, and Wagner. As an example of the considerations by which this selection of names was determined, I may quote what he says with regard to one of these bones of the skull.

'With regard to the 'squamosal' (squamosum. Lat. pars squamosa ossis temporis.—Sommering), it might be asked why the term 'temporal' might not be retained for this bone. I reply, because that term has long been, and is now universally, understood in human austomy to signify a peculiarly anthropotomical coalesced congeries of bones, which includes the 'squamosal' together with the 'petrosal,' the 'tympanic,' the 'mastoid,' and the 'stylohyal.' It seems preferable, therefore, to restrict the signification of the term 'temporal' to the whole (in Man) of which the 'squamosal' is a part. To this part Cuvier has unfortunately applied the term 'temporal' in one class, and 'jugal' in another, and he has also transferred the term 'temporal' to a third equally distinct bone in fishes, while to increase the confusion M. Agassız has shifted the name to a fourth different bone in the skull of fishes. Whatever, therefore, may be the value assigned to the arguments which will be presently set forth, as to the special homologies of the 'pars squamosa ossis temporis,' I have felt compelled to express the conclusion by a definite term, and in the present instance, have selected that which recalls the best accepted anthropomorphical designation of the part; although 'squamosal' must be understood and applied in an arbitrary sense, and not as descriptive of a scale-like form; which, in reference to the bone so called, is rather its exceptional than normal figure in the vertebrate series.'

The principles which Mr Owen here adopts in the selection of names for the parts of the skeleton are wise and temperate. They agree with the aphorisms concerning the language of science which I published in the Philosophy of the Inductive Sciences, and Mr. Owen does me the great honour of quoting with ap-

serval some of those Aphorisms. I may perhaps take the Literary of remarking that the system of terms which be has constructed, may, according to our principles be called rather a Terminology than a Nomenclature that is they are analogous more nearly to the terms by watch testanists describe the parts and organs of thank than to the names by which they denote general are species. As we have seen in the History, plants as well as animals are surject to morphological laws; and the names which are given to organs in consequence of those laws are a part of the Terminology if the science. Nor is this distinction between Termipower and Numenciature with ut its use; for the rules of reviews and property in the selection of words in the two cases are different. The Nomenclature of genera and species may be arbitrary and casual, as is the case to a great extent in Botany and in Zoology, especially of tossi remains, names being given, for instance, simply as marks of honour to individuals. But in a Terminology, such a mode of derivation is not situessi le some significant analogy or idea must be ai-ptei, at least as the origin of the name, though not processarily true in all its apprications, as we have seen m the case of the 'squamosal' just quoted. This difference in the rules respecting two classes of scientific words is stated in the Aphorisms xiii and xiv concerming the Language of Science.

Province in the second

Such a Termine ogy of the bones of the skeletons of all vertebrates as Mr. Owen has thus propounded, cannot be otherwise than an immense acquisition to science, and a means of ascending from what we know already to wider truths and new morphological doctrines.

With regard to one of these doctrines, the resolution of the human head into vertebre. Mr. Owen now regards it as a great truth, and replies to the objections of Cuvier and M. Agassiz, in detail. He gives a Table in which the Bones of the Head are resolved into four vertebra, which he terms the Occipital,

^{*} Architype and Bomologies of the Vertebrate Steleton. 1848. p. 41

Parietal, Frontal, and Nasal Vertebra respectively. These four vertebræ agree in general with what Oken called the Ear vertebra, the Jaw-vertebra, the Eyevertebra, and the Nose vertebra, in his work On the Signification of the Bones of the Skull, published in 1807; and in various degrees, with similar views promulgated by Spix (1815), Bojanus (1818), Geoffroy (1824), Carus (1828). And I believe that these views, bold and fanciful as they at first appeared, have now been accepted by most of the principal physiotogists of our time.

But another aspect of this generalization has been propounded among physiologists; and has, like the others, been extended, systematized, and provided with a convenient language by Mr. Owen. Since animal skeletons are thus made up of vertebræ, and their parts are to be understood as developements of the parts of vertebræ, Geoffroy (1822), Carus (1828), Muller (1834), Cuvier (1835), had employed certain terms while speaking of such developements; Mr. Owen, in the Geological Transactions in 1838, while discussing the osteology of certain fossil Saurians, used terms of this kind, which are more systematic than those of his predecessors, and to which he has given currency by the quantity of valuable knowledge and thought which he has embodied in them,

According to his Terminology, a vertebra in its typical completeness, consists of a central part or centrum; at the back of this, two plates (the neural apophyses) and a third outward projecting piece (the neural spine), which three, with the centrum, form a canal for the spinal marrow; at the front of the centrum two other plates (the hæmal apophyses) and a projecting piece, forming a canal for a vascular trunk. Further lateral elements (pleuro-apophyses) and other projections, are in a certain sense dependent on these principal bones, besides which the vertebra may support diverging appendages. These parts of the vertebra are fixed together, so that a vertebra is

³ Archetype and Homologies of the Vertebrate Skeleton. 1848. p 81

by some anatomists described as a single bone; but the parts now mentioned are usually developed from distinct and independent centres, and are therefore

called by Mr. Owen 'autogenous' elements.

The General Homology of the vertebral skeleton is the reference of all the parts of a skeleton to their true types in a series of vertebræ; and thus, as spenal homology refers all the parts of skeletons to a given type of skeleton, say that of Man, general homology refers all the parts of every skeleton, say that of Man, to the parts of a series of Vertebræ. And thus as Oken propounded his views of the Head as a resolution of the Problem of the Signification of the B mes of the Head, so have we in like manner, for the purposes of General Homology, to solve the Problem of the Signification of Limbs. The whole of the animal being a string of vertebræ, what are arms and legs, hands and paws, claws and fingers, wings and fins, and the like! This inquiry Mr. Owen has pursued as a necessary part of his inquiries. In giving a public lecture upon the subject in 1849,4 he conceived that the phrase which I have just employed would not be clearly apprehended by an English Audience, and entitled his Discourse 'On the Nature of Limbs;' and in this discourse he explained the modifications by which the various kinds of limbs are derived from their rudiments in an archetypal skeleton, that is, a mere senes of vertebræ without head, arms, legs, wings, or fins.

Final Causes.

It has been mentioned in the History that in the discussions which took place concerning the Unity of Plan of animal structure, this principle was in some measure put in opposition to the principle of Final Causes. Morphology was opposed to Teleology. It is natural to ask whether the recent study of Morphology has affected this antithesis.

⁴ On the Nature of Lambs, a Discourse delivered at a Meeting of the Royal Institution, 1849.

If there be advocates of Final Causes in Physiology who would push their doctrine so far as to assert that every feature and every relation in the structure of animals have a purpose discoverable by man, such reasoners are liable to be perpetually thwarted and embarrassed by the progress of anatomical knowledge, for this progress often shows that an arrangement which had been explained and admired with reference to some purpose, exists also in cases where the purpose disappears; and again, that what had been noted as a special teleological arrangement is the result of a general morphological law. Thus to take an example given by Mr. Owen . that the ossincation of the head originates in several centers, and thus in its early stages admits of compression, has been pointed out as a provision to facilitate the birth of viviparous animals; but our view of this provision is disturbed, when we find that the same mode of the formation of the bony framework takes place in animals which are born from an egg. And the number of points from which ossification begins, depends in a wider sense on the general homology of the animal frame, according to which each part is composed of a certain number of autogenous vertebral elements. In this way, the admission of a new view as to Unity of Plan will almost necessarily displace or modify some of the old views respecting Final Causes.

But though the view of Final Causes is displaced, it is not obliterated; and especially if the advocate of Purpose is also ready to admit visible correspondences which have not a discoverable object, as well as contrivances which have. And in truth, how is it possible for the student of anatomy to shut his eyes to either of these two evident aspects of nature? The arm and hand of man are made for taking and holding, the wing of the sparrow is made for flying; and each is adapted to its end with subtle and manifest contrivance. There is plainly Design. But the arm of man and the wing of the sparrow correspond to each other in the most exact manner, bone for bone. Where is the Use or the Purpose of this correspondence? If it be said

that there may be a purpose though we do not see ', that is granted. But Final Causes for me are central vances of which we see the end; and nothing is added to the evidence of Design by the perception of a unity of plan which in no way tends to promote the design

It may be said that the design appears in the monfication of the plan in special ways for special purposes. —that the vertebral plan of an animal being given, the tore limbs are modified, in Man and in Sparrow, as the nature and life of each require. And this is truly said, and is indeed the truth which we are endeavouring to bring into view.—that there are, in such speculations, two elements; one given, the other to be worked out from our examination of the case; the datum and the problem; the homology and the teleology.

Mr. Owen, who has done so much for the former of these portions of our knowledge, has also been constantly at the same time contributing to the other While he has been aiding our advances towards the Unity of Nature, he has been ever above to the percention of an Intelligence which pervades Nature While his morphological doctrines have moved the point of view from which he sees Design, they have never obscured his view of it, but, on the contrars, have led him to present it to his readers in new and striking aspects. Thus he has pointed out the final purposes in the different centers of ossification of the long bones of the limbs of mammals, and shown how and why they diff r in this respect from reptiles (Archetype, p. 104). And in this way he has been able to point out the insufficiency of the rule buil down both by Geoffroy St. Hilaire, and Cuvier, for ascertaining the true number of bones in each species.

Final Causes, or Evidences of Design, appear, as we have said, not merely as contrivances for evident purposes, but as modifications of a given general Plan for special given ends. If the general Plan be discovered after the contrivance has been noticed, the discovery may at first seem to obscure our perception of Purpose but it will soon be found that it merely transfers us to a higher point of view. The adaptation of the Means

PHYSIOLOGY AND COMPARATIVE ANATOMY. 561

nore general scheme than we were aware of. No generalization of the Means can or ought permanently to hake our conviction of the End; because we must needs suppose that the Intelligence which contemplates the End is an Intelligence which can see at a glance along a vista of Means, however long and complex. And on the other hand, no special contrivance, however clear be its arrangement, can be unconnected with the general correspondences and harmonies by which all parts of nature are pervaded and bound together. And thus no luminous teleological point can be extinguished by homology; nor, on the other hand, can it be detached from the general expanse of homological

light.

The reference to Final Causes is sometimes spoken of as unphilosophical, in consequence of Francis Bacon's comparison of Final Causes in Physics to Vestal Virgins, devoted to God, and barren. I have repeatedly shown that, in Physiology, almost all the great discoveries which have been made, have been made by the assumption of a purpose in animal structures. With reference to Bacon's simily. I have elsewhere said that if he had had occasion to develope its bearings, full of latent meaning as his similies so often are, he would probably have said that to those Final Causes barrenness was no reproach, seeing they ought to be not the Mothers but the Daughters of our Natural Sciences; and that they were barren, not by imperfection of their nature, but in order that they might be kept pure and undefiled, and so fit ministers in the temple of God. I might add that in Physiology, if they are not Mothers, they are admirable Nurses; skilful and sagacious in perceiving the signs of pregnancy, and helpful in bringing the Infant Truth into the light of day.

There is another aspect of the doctrine of the Archetypal Unity of Composition of Animals, by which it
points to an Intelligence from which the frame of
Nature proceeds; namely this:—that the Archetype
of the Animal Structure being of the nature of an Idea,
implies a mind in which this Idea existed; and that

FOL. III.

ADDITIONS.

rus Homology itself points the way to the lind. But while we acknowledge the full wais view of theological bearing of physiology, wenture to say that it is a view quite different that which is described by speaking of 'Final' and one much more difficult to present in the content of ordinary minds.

BOOK XVIII.

GEOLOGY.

WITH regard to Geology, as a Palætiological Science, I do not know that any new light of an important kind has been thrown upon the general doctrines of the science. Surveys and examinations of special phenomena and special districts have been carried on with activity and intelligence; and the animals of which the remains people the strata, have been reconstructed by the skill and knowledge of zoologists:—of such reconstructions we have, for instance, a fine assemblage in the publications of the Palæontological Society. But the great questions of the manner of the creation and succession of animal and vegetable species upon the earth remain, I think, at the point at which they were when I published the last edition of the History.

I may notice the views propounded by some chemists of certain bearings of Mineralogy upon Geology. As we have, in mineral masses, organic remains of former organized beings, so have we crystalline remains of former crystals; namely, what are commonly called pseudomorphoses - the shape of one crystal in the substance of another. M. G. Bischoff! considers the study of pseudomorphs as important in geology, and as frequently the only means of tracing processes which have taken place and are still going on in the mineral

kingdom.

I may notice also Professor Breithaupt's researches on the order of succession of different minerals, by observing the mode in which they occur and the order in which different crystals have been deposited, promise to be of great use in following out the geological changes which the crust of the globe has undergone. (Die Paragenesis der Mineralien. Freiberg. 1849)

^{1 (&#}x27;Aemicul and Physical Geology.

In conjunction with these may be taken M. de Senarmont's experiments on the formation of numerals in veins, and besides Bischoff's Chemical Geology Sartorius von Walterhausen's Observations on the occurrence of numerals in Amygdaloid.

As a recent example of speculations concerning Botanical Palectiology, I may give Dr. Hooker's views of the probable history of the Flora of the Pacific.

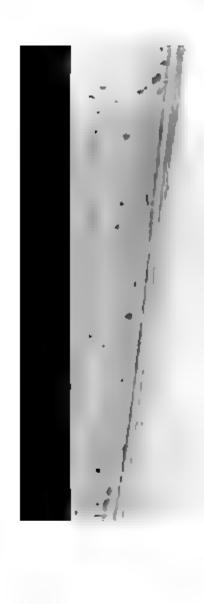

In speculating upon this question, Dr. Hooker is led to the discussion of geological doctrines concerning the former continuity of tracts of land which are now separate, the elevation of low lands into mountain ranges in the course of ages, and the like. We have already seen, in the speculations of the late lamented Edward Forbes, (see Book xvm. chap, vi. of this History,) an example of a hypothesis propounded to account for the existing Flora of England; a hypothesis, namely, of a former Connexion of the West of the British Isles with Portugal, of the Ales of Scotland with those of Scandinavia, and of the plains of East Anglia with those of Holland. In like manner Dr. Hooker says (p. xxi) that he was led to speculate on the possibility of the plants of the Southern Ocean being the remains of a Flora that had once spread over a larger and more continuous tract of land than now exists in the ocean; and that the peculiar Antarctic genera and species may be the vestiges of a Flora characterized by the predominance of plants which are now scattered throughout the Southern islands. He conceives this hypothesis to be greatly supported by the observations and reasonings of Mr. Darwin, tending to show that such risings and sinkings are in active progress over large portions of the continents and islands of the Southern hemisphere and by the speculations of Sir C Lyell respecting the influence of climate on the migrations of plants and animals, and the influence of geological changes upon climate.

In Zoology I may notice (following Mr. Owen)2 recent

³ Best. Aug. 1854, p. 112.

discoveries of the remains of the animals which come nearest to man in their structure. At the time of Cuvier's death, in 1832, no evidence had been obtained of fossil Quadrumana; and he supposed that these, as well as Bimana, were of very recent introduction. Soon after, in the oldest (cocene) tertiary deposits of Suffolk, remains were found proving the existence of a monkey of the genus Macacus. In the Himalayan tertiaries were found petrified bones of a Semnopithecus; in Brazil, remains of an extinct platyrhine monkey of great size; and lastly, in the middle tertiary series of the South of France was discovered a fragment of the jaw of the long-armed ape (Hylobates). But no fossil human remains have been discovered in the regularly deposited layers of any of the divisions (not even the pliocene) of the tertiary series; and thus we have evidence that the placing of man on the earth was the last and peculiar act of Creation.
